**I. INTRODUCTION**

The charm quark plays a unique role in the standard model. Since the top quark decays before it can hadronize [1], charm is the only up-type quark whose hadronic weak decays can be analyzed. The D sector thus offers the only handle to probe flavor-changing neutral currents among weak-isospin up quarks. Mixing is by now well established in the charm sector [2–4] and has already provided severe constraints on some new physics models [5]. First experimental results on CP violation in \( D^0 \to \pi^+ \pi^- , K^+ K^- \) decays [6] caused a lot of attention among phenomenologists [7]; see e.g. Ref. [3] for an overview. However, after a recent update [8], the experimental results seem to be compatible with the standard model expectation, the first hints for direct CP violation have triggered a lot of interest, and charm phenomenology will remain an essential part of new physics searches due to its unique role as a probe for flavor-changing neutral currents among up-type quarks. Charm physics poses considerable theoretical challenges, because the charm mass is neither light nor truly heavy. The heavy quark expansion (HQE) provides a perturbative expansion in the inverse heavy quark mass for inclusive rates. It has proved to be very successful in the \( B \) sector, yet its validity for charm decays has often been questioned. We present results of a HQE study of D-meson lifetimes including NLO QCD and subleading \( 1/m_c \) corrections. We find good agreement with experimental data, but with huge hadronic uncertainties due to missing lattice input for hadronic matrix elements.

Even if new data indicate that direct CP violation in D-meson decays is compatible with the standard model expectation, the first hints for direct CP violation have triggered a lot of interest, and charm phenomenology will remain an essential part of new physics searches due to its unique role as a probe for flavor-changing neutral currents among up-type quarks. Charm physics poses considerable theoretical challenges, because the charm mass is neither light nor truly heavy. The heavy quark expansion (HQE) provides a perturbative expansion in the inverse heavy quark mass for inclusive rates. It has proved to be very successful in the \( B \) sector, yet its validity for charm decays has often been questioned. We present results of a HQE study of D-meson lifetimes including NLO QCD and subleading \( 1/m_c \) corrections. We find good agreement with experimental data, but with huge hadronic uncertainties due to missing lattice input for hadronic matrix elements.

(Received 27 May 2013; published 5 August 2013)
it is possible that final states with small momentum release like $\eta(958)\rho^+$ spoil the validity of the HQE in the case of $D^+_s$.

A calculation of subleading corrections in charm mixing within the framework of the HQE [28] likewise did not show signs of a breakdown of the perturbative approach. It turned out that the charm width difference did not show signs of a breakdown of the perturbative D case of enhancement of the $D$ contribution shown in Fig. 3(a) [35]. Here, the suppression of the Pauli interference effect was not accounted for, i.e. in today’s language, the authors have set $\langle E_3 \rangle$ constant and $\langle g \rangle$. In Ref. [38], the authors additionally included the Cabibbo-suppressed weak annihilation of $D^+$ and obtained for the effects of weak annihilation in $D^0$ and $D^+$

$$\frac{\tau(D^+)}{\tau(D^0)} \bigg|_{[38]} = 5.6–6.9, \quad \frac{\tau(D^+)}{\tau(D^0)} \bigg|_{PD012[27]} = 2.536 \pm 0.019. \quad (2)$$

One should keep in mind that Pauli interference, which is now known to be the dominant effect, is still neglected here. This shows what a severe overestimation these early analyses were.

Further studies of the Pauli interference effect [39] already obtained results similar to the later HQE treatments; however, they were still in a less formal fashion. The first systematic treatments were performed in the following years, when the idea of HQE was developed and was applied to charm decays [9,10,40]. The formula below represents the starting point of the HQE and was first presented in Ref. [9] with a sign error which was corrected in Ref. [40]:

$$\Gamma(D^+) = \frac{G_F^2}{2M_D} (D^+ | \frac{m_c^2}{64\pi^3} \frac{2C_1^+ + C_2^2}{3} \bar{c}c + \frac{m_c^2}{2\pi} [(C_1^+ + C_2^2)(\bar{c}\Gamma_{\mu} d)(\bar{d}\Gamma_{\mu} c) + \frac{2C_1^+ - C_2^2}{3} (\bar{c}\Gamma_{\mu} d)(\bar{d}\Gamma_{\mu} c)] | D^+). \quad (3)$$

We have rewritten this in the color-singlet and color-octet basis commonly used today for $\Delta C = 0$ operators. The leading term describes the decay of the free charm quark in the parton model, and the following term describes the $1/m_c^2$—suppressed effect of Pauli interference. Neglecting weak annihilation, the total decay rate for $D^0$ is given by the first term of this expression. The four quark operators have been evaluated in the vacuum insertion approximation. In the early analyses, the lifetime ratios were generally underestimated,

$$\frac{\tau(D^+)}{\tau(D^0)} \bigg|_{early\,HQE\,analyses} = 1.5, \quad (4)$$

which was mainly due to a too-small estimate for the decay constant $f_D = 160–170$ MeV. The present value
of $f_D = 212.7$ MeV yields $\tau(D^+)/\tau(D^0) = 2.2$, which drastically improves the consistency with experiments. In Ref. [41], the effects of hybrid renormalization were first included. This constitutes the present state of theory predictions for the ratio of $D^+$ and $D^0$ lifetimes. It was argued that $\tau(D^+)/\tau(D^0)$, which contradicted the experimental situation at that time. However, better experimental results quickly straightened out the charmed mesons’ lifetimes. It was further shown in Ref. [42] that the HQE was able to correctly reproduce the hierarchy of mesons’ lifetimes. It was argued in a number of reviews by Bigi et al. that the lifetimes of weakly decaying charmed hadrons can be accounted for within the HQE at least in a “semiquantitative” fashion [47–49].

Summing up, the HQE was successful in reproducing the observed pattern of charm hadron lifetimes and explaining the issue of gluonic bremsstrahlung enhancement. However, charm lifetimes have so far only been considered at leading order in QCD. Subleading $1/m_c$ corrections to the spectator effects were never studied in charm, although they are expected to be sizeable. There has never been a dedicated quantitative analysis of $\tau(D^+)/\tau(D^0)$. For the numerical estimations, the vacuum saturation approximation of the four quark operators has been invoked. Deviations from this were parametrized in Refs. [45,46], but never quantitatively examined in the charm sector. Also, the mass of the strange quark and the muon have generally been neglected. We aim to improve on this in a number of crucial points:

1. We include NLO QCD corrections, which considerably reduces the dependence on the renormalization scale. This required a NLO computation of the coefficients for the semileptonic weak annihilation in $D_s^+$ presented in Appendix A.

2. Bag parameters are introduced to allow for the matrix elements to differ from their vacuum insertion approximation value.

3. We compute subleading $1/m_s$ corrections to the spectator effects to investigate the convergence behavior of the HQE.

4. The effects of the strange quark and muon mass are fully included in the phase-space factors.

This improves the theory predictions for the lifetimes of $D$ mesons considerably.

### III. INCLUSIVE RATES FOR CHARMED HADRONS

The HQE provides an OPE-based framework for the description of inclusive decay rates of hadrons containing one heavy quark [9–17]. It yields an expansion of $\Gamma(H_Q)$ in $\Lambda/m_Q$, where $\Lambda$ denotes the hadronic scale expected to be of order $\Lambda_{QCD}$ and $m_Q$ denotes the heavy quark mass. The HQE is based on the concept of quark hadron duality [50]. We work under the assumption that duality holds and then confront the phenomenological results with experimental data.

Integrating out the $W$ boson, one obtains the following effective Hamiltonian describing $\Delta C = 1$ transitions (see e.g. Ref. [51] for a review):

$$H_{\text{eff}} = \frac{G_F}{\sqrt{2}} [C_1(\mu_1)Q_1 + C_2(\mu_1)Q_2 + Q_\pi + Q_\mu] + \text{H.c.}$$

(7)
The local $\Delta C = 1$ operators are

$$Q_1 = \bar{s}_j \gamma_\mu (1 - \gamma_5) c_i \bar{u}_i \gamma^\mu (1 - \gamma_5) d'_j,$$

$$Q_2 = \bar{s}_j \gamma_\mu (1 - \gamma_5) c_i \bar{u}_i \gamma^\mu (1 - \gamma_5) d'_j,$$

and

$$Q_i = \bar{s} \gamma_\mu (1 - \gamma_5) c \bar{t}_i \gamma^\mu (1 - \gamma_5) v,$$

with $d' = V_{ud} d + V_{us} s$ and $s' = V_{cs} s + V_{cd} d$. The Wilson coefficients $C_i$ have been computed at NLO QCD in Refs. [52,53] and at NNLO QCD in Ref. [54]. We will, however, only use the NLO expressions in the NDR scheme defined in Ref. [53] throughout this work. The HQE then integrates out the hard momenta of the final-state particles. We use the optical theorem to express the decay rate via the imaginary part of the forward scattering amplitude

$$\Gamma(H_c) = \frac{1}{2M_{H_c}} \left( H_c \left| \frac{1}{2} \int d^4 x T[H_{\text{eff}}(x) H_{\text{eff}}(0)] \right| H_c \right)$$

$$= \frac{1}{2M_{H_c}} \langle H_c | T | H_c \rangle.$$  

(10)

For small $x$, i.e. large energy release, the transition operator $T$ can then be expanded by an OPE [18]. The result is a series

$$T = T_0 + T_2 + T_3 + T_4 + \cdots,$$

(11)

where $T_n$ denotes the $1/m_c^n$—suppressed part of $T$. The leading term $T_0 = \sum c^{(f)}_i \bar{c} c$ describes the free charm decay. Here, no nonperturbative contributions are present, since the hadronic matrix element $\langle H_c | \bar{c} c | H_c \rangle = 1 + \mathcal{O}(1/m_c^2)$ is trivial. The corresponding Wilson coefficients $c^{(f)}_i$ have been determined for $b$ decays in Ref. [55] and can be easily adjusted to the charm sector. To this order, the lifetimes of all weakly decaying charmed hadrons are equal. We observe that no $T_1$ term is present, because the contribution of the respective operator $\bar{c} i \gamma_\mu c$ can be incorporated in the leading term $T_0$ by application of the equations of motion. The $1/m_c^2$—suppressed part takes the form [14]

$$\frac{1}{2M_{H_c}} \langle H_c | T_2 | H_c \rangle = \sum c^{(f)}_i \frac{\mu_{(c)}^2(H_c) - \mu_{(s)}^2(H_c)}{2m_c^2}$$

$$+ \sum 2 c^{(f)}_i \frac{\mu_{(c)}^2(H_c)}{m_c^2}.$$  

(12)

where the first term originates from the heavy quark effective theory (HQET) expansion of the dimension-3 matrix element $\langle H_c | \bar{c} c | H_c \rangle$. The hadronic parameters $\mu_{(c)}^2(H_c)$ and $\mu_{(s)}^2(H_c)$ are the matrix elements of the kinetic and chromomagnetic operators, respectively. To this order, lifetime differences between charmed mesons only arise through $SU(3)$ flavor breaking of the hadronic matrix elements. The dominant contributions originate at order $1/m_c^3$ from the Pauli interference and weak annihilation diagrams shown in Fig. 3. They describe $2 \rightarrow 2$ instead of $1 \rightarrow 3$ processes, and hence are phase-space enhanced by a factor of $16\pi^2$. We neglect further contributions of order $1/m_c^3$ that lack this enhancement. We decompose the $1/m_c^3$ part of the transition operator as

$$T_3 = T_3^{\text{PI}} + T_3^{\text{WA}_0} + T_3^{\text{WA}_1} + T_3^{\text{sing}}.$$  

(13)

The contribution $T_3^{\text{sing}}$ arises from strong interactions of the free quark decay with the spectator quark of the type shown in Fig. 4. The effect of $T_3^{\text{sing}}$ cancels in the considered lifetime ratios in the limit of $SU(3)$ flavor symmetry, since the corresponding dimension-6 operators are $SU(3)$ flavor singlets. The remaining terms are

FIG. 4. Sample diagram for $T_3^{\text{sing}}$. 

034004-4
The label $qq'$ in $F^{qq'}, \ldots, G_{qq'}^{qq'}$ refers to the flavors of the quarks in the $qq'$ loop in Fig. 3. The Wilson coefficients $F, G$ are functions of the mass ratio $z = m_q^2/m_c^2$ and $\mu_0/m_c$, where $\mu_0$ denotes the renormalization scale for $\Delta C = 0$ operators. These dimension-6 operators read as follows:

$$Q^i = \bar{c} \gamma_\mu (1 - \gamma_5) q \bar{q} \gamma_\mu (1 - \gamma_5) c,$$

$$Q^i_S = \bar{c} (1 - \gamma_5) q \bar{q} (1 + \gamma_5) c,$$

$$T^i = \bar{c} \gamma_\mu (1 - \gamma_5) T^a q \bar{q} \gamma_\mu (1 - \gamma_5) T^a c,$$

$$T^i_S = \bar{c} (1 - \gamma_5) T^a q \bar{q} (1 + \gamma_5) T^a c.$$  

(A15)

The LO Wilson coefficients $F^{qq'}, \ldots, G_{qq'}^{qq'}$ for $B$ mesons can be found in Refs. [56,57]. The NLO QCQ corrections have been computed in Refs. [23,43]. The Wilson coefficients $F^{qq'}, \ldots, G_{qq'}^{qq'}$ for WA, have been calculated at LO QCQ for the $B_s$ meson in Ref. [58]. The NLO corrections for the nonleptonic WA can be determined from the published results via a Fierz transformation of the $\Delta C = 1$ operators given in Eq. (8). With our choice of evanescent

operators [53], the Fierz symmetry is respected at the one-loop level. This allows us to obtain the following relation between Wilson coefficients, that holds up to NLO:

$$(F^{ud}, F^{ud}_S, G_{uu}^{ud}, G_{uu}^{ud})$$

$$(F^{ud}, F^{ud}_S, G_{uu}^{ud}, G_{uu}^{ud})(C_1 \leftrightarrow C_2, m_s = 0),$$  

(A16)

where $C_1, C_2$ are the Wilson coefficients of the respective $\Delta C = 1$ operator. The NLO corrections for the semileptonic weak annihilation $F^{vl}, \ldots, G_{vl}^{vl}$ have been computed for the first time and are given in Appendix A.

The subleading $1/m_c^2$ contribution of the HQE is expected to be sizeable in the charm sector. It furthermore provides a crucial test of the convergence properties of the expansion. This contribution is the leading correction in an expansion of the spectator effects in the momentum and mass of the spectator quark. Applying the same decomposition as for $T_3$, we find

$$T_3^{pl} = \frac{G_F^2 m_c^2}{6 \pi} \sum_{d' = d, s} \sum_{q' = d, s} |V_{cq}|^2 |V_{uq'}|^2 \sum_{i = 1}^{6} (g^{q'u}_{i} P_i^{q'} + h^{q'u}_{i} S_i^{q'}),$$

$$T_3^{WA} = \frac{G_F^2 m_c^2}{6 \pi} \sum_{q = d, s} \sum_{q' = d, s} |V_{cq}|^2 |V_{uq'}|^2 \sum_{i = 1}^{6} (g^{q'u}_{i} P_i^{q'} + h^{q'u}_{i} S_i^{q'}),$$

$$T_3^{WA'} = \frac{G_F^2 m_c^2}{6 \pi} \sum_{s' = d, s} |V_{cs'}|^2 \sum_{i = 1}^{6} \sum_{q = d, s} |V_{uq'}|^2 (g^{q'u}_{i} P_i^{q'} + h^{q'u}_{i} S_i^{q'}) + \sum_{l = e, \mu} \left( g^{pl}_{i} P_i^{l'} + h^{pl}_{i} S_i^{l'} \right).$$  

(A17)

The dimension-7 operators and Wilson coefficients are given in Appendix B. For the case of QCD operators (see the discussion at the end of this section), this contribution has previously been determined in Ref. [59] using a different operator basis.

A comment about the $T_3$ term is in order. In addition to the kinetic corrections, there is also a chromomagnetic contribution to the spectator effects. The kinetic corrections can be computed in the same fashion as for $T_4$ and are found to be numerically unimportant. The chromomagnetic effects of the form shown in Fig. 5 can, however, not be estimated in the vacuum saturation approximation (VSA) [60]. But if these contributions are not severely enhanced compared to the kinetic effects, the HQE can be truncated to good approximation after the $T_4$ term.

As stressed in Refs. [43,61], the two possible contractions shown in in Fig. 6 have to be considered when computing the matrix elements of the dimension-6 operators ($\bar{c}\Gamma \gamma_q q\bar{t} \Gamma'_c$) on the lattice. The eye contraction diagram induces mixing of the renormalized dimension-6 operators into lower-dimensional operators. The required power subtraction of this mixing poses considerable challenges for lattice computations. We therefore distinguish
between these two contributions in our parametrization of hadronic matrix elements in Appendix C. Such mixing also occurs in $T^{\text{sing}}$ at $O(\alpha_s)$ in perturbation theory. For dimensional reasons, this mixing has to be of the form $\propto \alpha_s(m_c) m_c^2 (\bar{c} c)$. In QCD, a perturbative subtraction of this term is necessary as discussed in Ref. [22]. A NLO computation of $T^{\text{sing}}$ has not been performed so far and is also beyond the scope of this work. Yet, in the ratio $\tau(D^+)/\tau(D^0)$, the contribution of $T^{\text{sing}}$ and the eye contraction cancel due to isospin symmetry. Unfortunately, the deviations from exact $SU(3)$ flavor symmetry are too large in $\tau(D^+_s)/\tau(D^0)$ to be ignored. For the analysis of $\tau(D^+_s)/\tau(D^0)$, we thus match the QCD operators to HQET operators, where the natural cutoff due to the limit $m_c \rightarrow \infty$ guarantees the absence of mixing with lower-dimensional operators in perturbation theory [22,43,61].

A HQET description of operators, however, affects the subleading $1/m_c$ corrections, because the QCD operators $\bar{c} q q \Gamma c$ coincide with the respective HQET operators only up to $1/m_c$ corrections. The expansion of the QCD operators in HQET yields

$$\tilde{\Gamma} q q \Gamma c = \tilde{h}_v \Gamma q q \Gamma h_v \left[ 2m_c \right] + \frac{1}{m_c} \left[ \tilde{h}_v (-i\bar{\psi}) q q \Gamma h_v \right] + O\left( \frac{1}{m_c^2} \right).$$

The operators arising this way are $P^q_{5,6}$ and $S^q_{5,6}$ in Eq. (B1). The respective terms are absent in QCD when the hadronic matrix elements are determined to all orders in $1/m_c$.

IV. PHENOMENOLOGY

We perform an analysis of the lifetime ratios $\tau(D^+)/\tau(D^0)$ and $\tau(D^+_s)/\tau(D^0)$. Since the pole mass definition contains an infrared renormalon ambiguity [62,63], we use the ${\overline{\text{MS}}}$ in addition to the pole mass scheme. In the ${\overline{\text{MS}}}$ scheme, we use $\tilde{z} = m_c^2 (m_c)/m_c^2 (m_c)$. As discussed in detail in Ref. [23], this sums up terms of the form $\alpha_s^2 (\mu) z \ln^n z$ to all orders in perturbation theory.

A. The ratio $\tau(D^+)/\tau(D^0)$

We determine the ratio $\tau(D^+)/\tau(D^0)$, first using QCD operators, and then briefly discuss the HQET case. Isospin symmetry implies the following relations:

$$\frac{\langle D^0 \rangle (\tilde{Q}, \tilde{P}, \tilde{S})^a d | D^0 \rangle}{2M_{D^0}} = \frac{\langle D^0 \rangle (\tilde{Q}, \tilde{P}, \tilde{S})^b u | D^0 \rangle}{2M_{D^0}}.$$  

From Eqs. (14) and (17), and (C1) and (C2), we obtain $\tau(D^+)/\tau(D^0)$:

$$\Gamma(D^0) - \Gamma(D^+) = \frac{G_F m_c^2}{12\pi} f_D^2 M_D \left[ (\tilde{F}^{\ell d} - |V_{ud}|^2 \tilde{F}^{\ell u}) \cdot \tilde{B} + \frac{M_D - m_c}{m_c} (\tilde{F}^{\ell d} - |V_{ud}|^2 \tilde{F}^{\ell u}) \cdot \tilde{B} \right].$$  

For brevity, we have introduced the vector notation

$$\tilde{F}^{qq'} = \begin{pmatrix} F^{qq'} \\ F_3^{qq'} \\ G^{qq'} \\ G_3^{qq'} \end{pmatrix}, \quad \tilde{B} = \begin{pmatrix} B_1 \\ B_2 \\ \epsilon_1 \\ \epsilon_2 \end{pmatrix},$$

$$\tilde{f}^{qq'} = \begin{pmatrix} f^{qq'} \\ f_3^{qq'} \\ h^{qq'} \\ h_3^{qq'} \end{pmatrix}, \quad \tilde{b} = \begin{pmatrix} -\rho_3 \\ \rho_4 \\ -\sigma_3 \\ \sigma_4 \end{pmatrix}. $$

The NLO QCD correction to $\tilde{F}^{qq}$ has not been determined. Following Ref. [23], we thus set $|V_{ud}|^2 = 1$ and $V_{us} = 0$ in...
the NLO term. The induced error is of order $|V_{ud}|^2 \alpha_s(m_c) \varepsilon \log \varepsilon$, which is of order $10^{-3}$ and thus negligible. Furthermore, the Cabibbo and chirality-suppressed weak annihilation contribution to $D^+$ is neglected. The matrix elements of the $\Delta C = \pm 1$ operators can be estimated within the VSA [60]. The uncertainties are expected to be of order $1/N_c$, although calculations in the $B$ sector [61,64,65] hint at much smaller errors for the color octet operators. Thus, using

$$ (B_1, B_2, \epsilon_1, \epsilon_2) = \left( 1 \pm \frac{1}{3}, \left(1 + 2 \frac{M_D - m_c}{m_c} \right) \left(1 \pm \frac{1}{3}\right) \right), $$

$$ (\rho_3, \rho_4, \sigma_3, \sigma_4) = \left( 1 \pm \frac{1}{3}, 1 \pm \frac{1}{3}, 0 \pm \frac{1}{10}, 0 \pm \frac{1}{10} \right), $$

we obtain in the pole and $\overline{\text{MS}}$ mass schemes with the input parameters given in Table I:

$$ \left( \frac{\Gamma(D^+)}{\Gamma(D^0)} \right)_{\text{pole, VSA}} = 1.9 \pm 1.7^{(\text{hadronic})} + 0.6^{(\text{scale})} \pm 0.0^{(\text{parametric})}, $$

$$ \left( \frac{\Gamma(D^+)}{\Gamma(D^0)} \right)_{\text{MS, VSA}} = 2.2 \pm 1.7^{(\text{hadronic})} + 0.3^{(\text{scale})} \pm 0.1^{(\text{parametric})}. $$

(23)

The dependence on the renormalization scale of the $\Delta C = \pm 1$ operators is illustrated in Fig. 7. It is dominated by the scale dependence of the subleading dimension-7 contributions, because they are only evaluated at LO QCD. Also, the difference between the expectation values in the pole mass and $\overline{\text{MS}}$ mass scheme originates dominantly from $\Gamma_4$. The $\mu_1$ dependence of Fig. 7 suggests that we have varied $\mu_0$ and $\mu_1$ from 1 GeV to $2m_c$. We do not use the full region $0.5m_Q - 2m_Q$ common in $B$ decays, because we do not trust perturbation theory to hold below about 1 GeV. The overall error is largely driven by hadronic uncertainties. The size of the subleading $1/m_c$ corrections relative to the leading spectator effects is an important check on the convergence behavior. We find that

$$ \frac{\Gamma_4^{(0)}(D^0) - \Gamma_4^{(0)}(D^+)}{\Gamma_3^{(0)}(D^0) - \Gamma_3^{(0)}(D^+)} \approx -50\%, $$

(24)

which is large, but compatible with a convergent series. The $1/m_c^2$ term should be numerically less relevant, as discussed in Sec. III. Next-to-leading-order QCD corrections to $T_3$ are at a level of below 30% near the charm scale.

The predictive power of the VSA is very limited. In the following, we perform a very aggressive estimation of $\Gamma(D^+)/\Gamma(D^0)$ by extracting the bag parameters from a lattice calculation in the $B$ sector [61] and ignore any possible systematic uncertainties related with this approach. We extract the bag parameters for a meson mass of $m_P = 1.8$ GeV and a hadronic scale $\mu_0 = 2.7$ GeV from Ref. [61] and evaluate this to the charm scale $\mu_0 = m_c$ at NLO. The required anomalous dimension matrices can be inferred from Ref. [66]. This reduces the hadronic uncertainty considerably:

$$ \left( \frac{\Gamma(D^+)}{\Gamma(D^0)} \right)_{\text{pole, extr from [61]}} = 1.9 \pm 0.5^{(\text{hadronic})} + 0.6^{(\text{scale})} \pm 0.0^{(\text{parametric})}, $$

$$ \left( \frac{\Gamma(D^+)}{\Gamma(D^0)} \right)_{\text{MS, extr from [61]}} = 2.2 \pm 0.4^{(\text{hadronic})} + 0.3^{(\text{scale})} \pm 0.0^{(\text{parametric})}. $$

(25)

perturbation theory becomes unreliable at about 1 GeV, but it seems to be under control at the charm threshold. We see a substantial reduction of the theoretical uncertainties from the VSA to the extracted matrix elements. The equality of the central values is coincidental.

In HQET, we get an expression similar to Eq. (20) for $\Gamma(D^+)/\Gamma(D^0)$:

$$ \Gamma(D^0) - \Gamma(D^+) = \frac{G^2 m_c^2}{12\pi} \int_D^2 M_D \left[ (\tilde{F}^{u'd'} - |V_{ud}|^2 \tilde{F}^{s'u'}) - |V_{cd}|^2(\tilde{F}^{u'd'} + \tilde{F}^{s'u'}) \right] \cdot B $$

$$ + \frac{M_D - m_c}{m_c} \sum_{j=3}^6 (-1)^j \left[ (g_j u' - |V_{ud}|^2 g_j s') - |V_{cd}|^2(g_j u' + g_j s') \right] \rho_j + (g_j \to h_j, \rho_j \to \sigma_j). $$

(26)
The sizeable differences between the HQET and the QCD results in the VSA seem puzzling at first, but we have to remember that the matrix elements are defined in a different scheme. The transformation law for the dimension-6 Wilson coefficients is given in Refs. [23,43]. We have checked explicitly that this relation holds for our numerical coefficients, if in HQET we neglect weak annihilation in $D_\pi^+$ and set $|V_{ud}|^2 = 1$, $V_{us} = 0$ at NLO as we have in QCD. This scheme dependence is canceled by the scheme dependence of the operators. The VSA is, however, not sensitive to the scheme, and the numerical deviation between Eqs. (23) and (27) is just a consequence of this. This once more emphasizes the dire need for lattice inputs for the matrix elements.

**B. The ratio $\tau(D_\pi^+)/\tau(D^0)$**

Since $SU(3)$ flavor symmetry is rather crude in the case of $\tau(D_\pi^+)/\tau(D^0)$, the contributions of $T^{sing}$ and the eye contraction do not fully cancel as was the case in $\tau(D^+)/\tau(D^0)$. We hence use only HQET operators in the following analysis. The dominant sources for the lifetime difference between these mesons have been identified in Ref. [45]. We further include (e), which could possibly contribute at the level of a few percent.

(a) The decay $D_\pi^+ \to \tau^+ \nu$
(b) $SU(3)$ flavor breaking in $\mu_{\tau}^2$ and $\mu_G^2$
(c) The weak annihilation in $D^0$ and $D_\pi^+$
(d) The Cabibbo-suppressed Pauli interference in $D_\pi^+$
(e) $SU(3)$ flavor breaking in the nonvalence part of the $c\bar{d}$ Pauli interference.

The first effect (a) cannot be properly dealt with in the HQE, because the energy release in $D_\pi^+ \to \tau^+ \nu$ is just $\sim 200$ MeV. Instead, we define a subtracted $D_\pi^+$ lifetime by

$$\hat{\tau}(D_\pi^+) = \frac{\tau(D_\pi^+)}{1 - \text{Br}(D_\pi^+ \to \tau^+ \nu)} = (529 \pm 8) \times 10^{-15} \text{ s}$$

and compare our prediction with $\hat{\tau}(D_\pi^+)/\tau(D^0)$.

$SU(3)$ flavor breaking in $\tau(D_\pi^+)/\tau(D^0)$ arises at order $(\Lambda/m_c)^2$ in the HQE. We follow Ref. [67] to extract the corresponding matrix elements of the dimension-5 operators from experimental data. The expectation value $\mu_G^2$ of the chromomagnetic operator can be extracted from the hyperfine splitting. We find, using the meson masses given in Ref. [27],

$$\frac{\mu_G^2(D_\pi^+)}{\mu_G^2(D^0)} \simeq \frac{M_{D^*_\pi} - M_{D^+}}{M_{D^0} - M_D} = 1.012 \pm 0.003.$$  

The effects of $1/m_c$ corrections should cancel to a large extent in the ratio in Eq. (29). Regarding the overall uncertainties, this effect can safely be neglected. The situation in the case of the kinetic operator is less clear. Yet we can estimate the difference $\mu_{\tau}^2(D_\pi^+) - \mu_{\tau}^2(D)$ from spectroscopy. We obtain
\[
\mu_\pi^2(D_s^-) - \mu_\pi^2(D^0) \\
\approx \frac{2m_h m_c}{m_h - m_c} \left[ (\langle M_{D_s^-}^2 \rangle - \langle M_{D^0}^2 \rangle) - (\langle M_{D_s^+}^2 \rangle - \langle M_{B^+}^2 \rangle) \right] \\
= (0.07 \pm 0.01) \text{ GeV}^2,
\]

which corresponds to about 25\% \text{SU}(3) flavor breaking in \( \mu_\pi^2 \). Fortunately, this effect can be included at NLO independent of the coefficients \( c_i^f \):

\[
\frac{\bar{\tau}(D_s^+) - \bar{\tau}(D^0)}{\bar{\tau}(D^0)} - 1 = \frac{G_F^2 m_s^5}{192 \pi^3} \sum_j |V_{CKM}^j|^2 \frac{c^f_j \mu_\pi^2(D_s^+) - \mu_\pi^2(D^0)}{2m_c^2} \\
+ (c^f_3 + 4c^f_5) \frac{\mu_\pi^2(D^0) - \mu_\pi^2(D_s^+)}{2m_c^2} \\
+ O\left( \frac{1}{m_c^2} \right) \cdot \bar{\tau}(D_s^+). \tag{32}
\]

Numerically, we find

\[
\frac{\bar{\tau}(D_s^+) - \bar{\tau}(D^0)}{\bar{\tau}(D^0)} - 1 = \begin{cases} 
0.19^{+0.04}_{-0.03} \text{ GeV}^2 & \text{pole scheme}, \\
0.16^{+0.03}_{-0.02} \text{ GeV}^2 & \text{\overline{MS} mass scheme}, \end{cases} \tag{33}
\]

which enhances \( \bar{\tau}(D_s^+)/\bar{\tau}(D^0) \) by 2\% for \( \mu_\pi^2(D_s^+) - \mu_\pi^2(D^0) = 0.1 \text{ GeV}^2 \).

The weak annihilation effects (c) are Cabibbo leading, but do suffer from chirality suppression. Chirality breaking stems from final-state masses and QCD effects. Since the mass ratio \( z = m_s^2/m_c^2 \) is rather small, the NLO corrections to the Wilson coefficients are very important here to obtain a meaningful result. The weak annihilation contributions are given by

\[
[\Gamma(D^0) - \Gamma(D_s^+)]_{WA(D_s^+)} = \frac{G_F^2 m_s^2}{12 \pi} f_{D_s}^2 M_{D_s} \left| V_{c s} \right|^2 \left[ \tilde{F}^\mu_{\text{u}d} + \tilde{F}^\nu_{\text{r}e} + \tilde{F}^\rho_{\text{\mu}d} \right] \cdot (\tilde{B}^s + \Delta \tilde{B}) \\
+ \sum_{j=1}^6 M_j \left[ (g_{j}^{\text{u}d} + g_{j}^{\text{r}e} + g_{j}^{\text{\mu}d}) (\rho_{j}^s + \Delta \delta_{\rho,j}) \\
+ (h_{j}^{\text{u}d} + h_{j}^{\text{r}e} + h_{j}^{\text{\mu}d}) (\sigma_{j}^s + \Delta \delta_{\sigma,j}) \right] \tag{34}
\]

for \( D_s^+ \) and

\[
[\Gamma(D^0) - \Gamma(D_s^+)]_{WA(D_s^+)} = \frac{G_F^2 m_s^2}{12 \pi} f_{D_s}^2 M_{D_s} \left[ \tilde{F}^\mu_{\text{u}d} + \tilde{F}^\nu_{\text{r}e} + \tilde{F}^\rho_{\text{\mu}d} \right] \\
+ \sum_{j=1}^6 M_j \left[ (g_{j}^{\text{u}d} + g_{j}^{\text{r}e} + g_{j}^{\text{\mu}d}) (\rho_{j}^s + \Delta \delta_{\rho,j}) \\
+ (h_{j}^{\text{u}d} + h_{j}^{\text{r}e} + h_{j}^{\text{\mu}d}) (\sigma_{j}^s + \Delta \delta_{\sigma,j}) \right] \tag{35}
\]

for \( D^0 \). We have introduced the following notation:

\[
M_j = \begin{cases} 
- m_{c_j}, & j = 1, 2, \\
(-1)^j \frac{m_{d_j}}{m_c}, & j = 3, 4, \\
(-1)^j \frac{m_{d_j}}{m_c}, & j = 5, 6. \end{cases} \tag{36}
\]

The \( \delta_\rho^{u,d} \) only enter in the \text{SU}(3)-breaking combinations

\[
\Delta \delta_{\rho,(\rho,a)}^{u,s} = \tilde{\delta}_{\rho,(\rho,a)}^{u,s} - \frac{f_D^2 M_D}{f_{D_s}^2 M_{D_s}} \tilde{\delta}_{\rho,(\rho,a)}^{u,s},
\]

\[
\Delta \delta_{(\rho,a)}^{s,u} = \tilde{\delta}_{(\rho,a)}^{s,u} - \frac{f_D^2 M_D}{f_{D_s}^2 M_{D_s}} \tilde{\delta}_{(\rho,a)}^{s,u}. \tag{37}
\]

These weak annihilation contributions depend strongly on the amount of chirality breaking through the matrix elements. Here, the VSA is far too crude, and we thus estimate this using experimental results for semileptonic rates similar to the study in Ref. [68]. They allow a very clean extraction of the chirality-breaking combinations \( B_1 - B_2 \) and \( \epsilon_1 - \epsilon_2 \). The experimental average for the ratios of semileptonic rates is

\[
\frac{\Gamma(D_s^+ \to X e^+ \nu)}{\Gamma(D^0 \to X e^+ \nu)} \bigg|_{[27]} = 0.821 \pm 0.054. \tag{38}
\]

The difference of the semileptonic rates arises first at order \( 1/m_c^2 \) in the HQE because of \text{SU}(3) flavor breaking. The dominant effect, however, is due to the semileptonic weak annihilation at order \( 1/m_c^2 \) and higher in the HQE. In terms of the required matrix elements, we obtain in the \overline{MS} mass scheme...
For the weak annihilation in $D_s^+$, we also reduce the parameter space to

$$
\frac{B_1 + \Delta \delta_1 + B_2 + \Delta \delta_2}{2} = 1 \pm \frac{1}{3}, \quad B_1 + \Delta \delta_1 - B_2 - \Delta \delta_2 = 0 \pm 0.1,
$$

$$
\frac{e_1 + \Delta \delta_3 + e_2 + \Delta \delta_4}{2} = 0 \pm 0.05, \quad e_1 + \Delta \delta_3 - e_2 - \Delta \delta_4 = 0 \pm 0.05,
$$

which is justified by the assumptions that the $\delta$’s are small and approximate SU(3) flavor symmetry. Numerically, we obtain for the weak annihilation in $D_s^+$

$$
\left( \frac{\tilde{\tau}(D_s^+) - 1}{\tau(D^0)} \right)_{WA(D_s^+)} = \begin{cases} 
0.12 \pm 0.06^{(\text{hadronic})} \pm 0.02^{(\text{scale})} \pm 0.00^{(\text{parametric})}, & \text{pole mass scheme,} \\
0.12 \pm 0.06^{(\text{hadronic})} \pm 0.01^{(\text{scale})} \pm 0.00^{(\text{parametric})}, & \text{MS mass scheme,}
\end{cases}
$$

and for the weak annihilation in $D^0$

$$
\left( \frac{\tilde{\tau}(D_s^+) - 1}{\tau(D^0)} \right)_{WA(D^0)} = \begin{cases} 
-0.01 \pm 0.08^{(\text{hadronic})} \pm 0.00^{(\text{scale})} \pm 0.00^{(\text{parametric})}, & \text{pole mass scheme,} \\
-0.01 \pm 0.08^{(\text{hadronic})} \pm 0.00^{(\text{scale})} \pm 0.00^{(\text{parametric})}, & \text{MS mass scheme.}
\end{cases}
$$

The contribution (d) from Pauli interference in $D_s^+$ is Cabibbo suppressed and should therefore only affect the lifetime difference at the order of a few percent. It is given by
\[ G(D^0) \equiv \frac{G_F m_c^2}{12\pi} f_{D_c}^2 M_{D_c} |V_{u d}| \left[ \vec{F}^{u u} \cdot (\hat{B}^+ + \Delta \tilde{B}) + \sum_{j=1}^{6} M_j \left[ g^{u u}_{j} (\rho^+ + \Delta \rho_{p,j}) + h^{u u}_{j} (\sigma^+ + \Delta \sigma_{p,j}) \right] \right] \]  

(45)

This yields

\[
\frac{\tilde{\tau}(D^+)}{\tau(D^0)} = 1.289 - 0.019,
\]

\[
\frac{\tilde{\tau}(D^{+}_{c})}{\tau(D^{0})}_{\text{pole mass scheme}} = 1.18 - 0.13_r^{\text{hadronic}}(0.04)^{\text{(scale)}} \pm 0.01_r^{\text{parametric}},
\]

\[
\frac{\tilde{\tau}(D^{+}_{c})}{\tau(D^{0})}_{\text{MS}} = 1.19 - 0.12_r^{\text{hadronic}}(0.04)^{\text{(scale)}} \pm 0.01_r^{\text{parametric}}.
\]

(48)

The theory prediction falls a bit short of the experimental value, but within the theory uncertainty it is well consistent.

V. CONCLUSION

In this work, we investigated the validity of the HQE in the charm sector using D-meson lifetimes. In the B sector the HQE is well tested, but doubts about the validity of the 1/m_c expansion have often been voiced. Because m_c \approx m_b/3, the convergence behavior of the HQE is obviously slower than for B hadrons. Therefore, we have considered subleading corrections in the 1/m_c expansion as well as NLO QCD corrections. For \( \tau(D^+)/\tau(D^0) \), we found very good agreement with experimental data:

\[
\frac{\tau(D^+)}{\tau(D^0)} = 2.530 - 0.019,
\]

(49)

However, an update of hadronic \( \Delta C = 0 \) matrix elements is direly needed given the advances lattice QCD has made in the past decade. For the \( \Delta C = 2 \) matrix elements required in \( D^0 - D^0 \) mixing, such a computation has recently been performed with high accuracy in Ref. [69]. We estimate that the remaining scale dependence could be considerably reduced by a NLO calculation of the dimension-7 Wilson coefficients. However, this is only worthwhile if simultaneous progress on dimension-7 matrix elements is made.

The low-momentum release decay \( D^+_c \rightarrow \eta'(958) \rho^+ \) poses a potential threat to the HQE description of the \( D^+_c \) lifetime. Thus, we would expect a possible failure of the HQE to be most apparent here. We found that the HQE result for the \( D^+_c - D^0 \) lifetime ratio falls slightly short of the experimental value, but it is consistent within hadronic uncertainties:

\[
\frac{\tilde{\tau}(D^+_c)}{\tau(D^0)}_{\text{exp}} = 1.289 - 0.019,
\]

\[
\frac{\tilde{\tau}(D^+_c)}{\tau(D^0)}_{\text{MS, extr from [61]}} = 1.19 - 0.12_r^{\text{hadronic}}(0.04)^{\text{(scale)}} \pm 0.01_r^{\text{parametric}}.
\]

(50)

Presently, however, this does not exclude possible large violations of the HQE. A nonperturbative determination
of the hadronic matrix elements could provide a more stringent upper bound. In addition, this would offer the unique possibility to use semileptonic decays, where the momentum release is large, to extract information on the nonvalence contractions. This is not possible in $B$ decays, because the semileptonic weak annihilation is doubly CKM suppressed and the difference of the semileptonic widths is too small to be measured experimentally. The subleading corrections to the lifetimes are large (≈30\% QCD, ≈50\%/m_c), but still allow a description within the realm of perturbation theory. Similar behavior was found in an earlier study of $D^0$ – $\bar{D}^0$ mixing [28]. The analysis of the $\mu_1$ dependence of our results suggests that perturbation theory breaks down below about 1 GeV but still works at the charm scale. In combination with the intriguing agreement of the standard-model HQE prediction for $\Delta \Gamma_s$ with experiment in spite of the small momentum release, this justifies confidence in the validity of the HQE. Still, lattice inputs are crucial to confirming this view.

ACKNOWLEDGMENTS

We are grateful to U. Nierste for giving us access to a program from the computation in Ref. [23] that allowed us to check the results of Appendix A, for clarifying discussions, and for carefully reading the manuscript. We are thankful to V. Khoze, M. Voloshin, I. Bigi and in particular N. Uraltsev for various comments on the history of $D$-meson lifetimes. T.R. would like to thank G. Kirilin, J. Rohrwild and F. Krinner for helpful discussions, the IPPP Durham and KIT Karlsruhe for hospitality, and M. Beneke and A. Ibarra for support during his thesis.

APPENDIX A: NLO WILSON COEFFICIENTS FOR THE SEMILEPTONIC WEAK ANNIHILATION

We decompose the Wilson coefficients as

$$F_{\nu\mu}(0) = F_{\nu\mu}(0) + \frac{\alpha_s}{4\pi} F_{\nu\mu}(1), \ldots$$

The Wilson coefficients for the semileptonic weak annihilation in the scheme of Ref. [43] read

$$F_{\nu\mu}(0)(z) = -(1 - z)^2 \left(1 + \frac{z}{2}\right),$$
$$F_{\nu\mu}(0)(z) = (1 - z)^2 (1 + 2z),$$
$$\tilde{G}_{\nu\mu}(0)(z) = 0,$$
$$\tilde{G}_{\nu\mu}(0)(z) = 0,$$

and

$$\tilde{G}_{\nu\mu}(0)(z) = \frac{1}{18} ((1 - z)(-205 - 7z + 110z^2) - 6z^2(6 + 11z) \log(z)) - 3(1 - z)^2(2 + z) \left[ \log \left( \frac{\mu_0}{m_c} \right) - \log (1 - z) \right].$$

$$\tilde{G}_{\nu\mu}(0)(z) = \frac{1}{9} (1 - z)(95 + 104z - 211z^2) - \frac{4}{3} z^2(12 - 11z) \log(z) + 6(1 - z)^2(1 + 2z) \left[ \log \left( \frac{\mu_0}{m_c} \right) - \log (1 - z) \right].$$

where $z = m_{\chi}^2 / m_c^2$. Note that our convention for the Wilson coefficients differs from that of Ref. [43] by a factor of 3. The details of the calculation have been described in Refs. [23,43]. We have checked the correctness of these coefficients against intermediate results from the computation in Ref. [23] kindly made available to us by Ulrich Nierste.

APPENDIX B: OPERATOR BASIS AND WILSON COEFFICIENTS FOR DIMENSION SEVEN

We use the following basis for the dimension-7 operators:

$$P_1^q = \frac{m_q}{m_c} \bar{c}(1 - \gamma_5)q \otimes \bar{q}(1 - \gamma_5)c,$$
$$P_2^q = \frac{m_q}{m_c} \bar{c}(1 + \gamma_5)q \otimes \bar{q}(1 + \gamma_5)c,$$
$$P_3^q = \frac{m_q}{m_c} \bar{c} \gamma_\mu (1 - \gamma_5)D^\mu q \otimes \bar{q} \gamma^\mu (1 - \gamma_5)c,$$
$$P_4^q = \frac{m_q}{m_c} \bar{c} \gamma_\mu (1 - \gamma_5)D^\mu q \otimes \bar{q} (1 + \gamma_5)c,$$
$$P_5^q = \frac{1}{m_c} \bar{c} \gamma_\mu (1 - \gamma_5)q \bar{q} \gamma^\mu (1 - \gamma_5)(i\bar{\Psi})c,$$
$$P_6^q = \frac{1}{m_c} \bar{c} (1 - \gamma_5)q \bar{q} (1 + \gamma_5)(i\bar{\Psi})c.$$
The $S_q^i$ are the corresponding color octet operators obtained by inserting $T^A$ in the two currents of the respective color singlet operators. As discussed at the end of Sec. III, the operators $P_Q^i$ and $S_{5,6}^q$ only occur in HQET and are absent if we use QCD operators. We decompose the Wilson coefficients for dimension seven defined in Eq. (25) as

$$g_{i}^{qq}(z) = C_1 g_{s,11}^{q,0} + C_2 g_{s,12}^{q,0} + C_3 g_{s,22}^{q,0} + O(\alpha_s). \tag{B2}$$

As results for the LO coefficients we obtain

$$\frac{1}{3} g_{s,11}^{d,0}(z) = \frac{1}{2} g_{s,12}^{d,0}(z) = 3 g_{s,22}^{d,0}(z) = \frac{1}{2} h_{s,12}^{d,0}(z) = - (1 - z)^2 (1 + 2z),$$

$$\frac{1}{3} g_{s,21}^{d,0}(z) = \frac{1}{2} g_{s,22}^{d,0}(z) = 3 g_{s,22}^{d,0}(z) = \frac{1}{2} h_{s,22}^{d,0}(z) = - (1 - z)^2 (1 + 2z),$$

$$\frac{1}{3} g_{s,31}^{d,0}(z) = \frac{1}{2} g_{s,32}^{d,0}(z) = 3 g_{s,32}^{d,0}(z) = \frac{1}{2} h_{s,32}^{d,0}(z) = 2 (1 - z) (1 + z + z^2),$$

$$\frac{1}{3} g_{s,41}^{d,0}(z) = \frac{1}{2} g_{s,42}^{d,0}(z) = 3 g_{s,42}^{d,0}(z) = \frac{1}{2} h_{s,42}^{d,0}(z) = - 12 z^2 (1 - z),$$

$$\frac{1}{3} g_{s,11}^{d,0}(z) = \frac{1}{2} g_{s,12}^{d,0}(z) = 3 g_{s,22}^{d,0}(z) = \frac{1}{2} h_{s,11}^{d,0}(z) = - \sqrt{1 - 4 z} (1 + 2z),$$

$$\frac{1}{3} g_{s,21}^{d,0}(z) = \frac{1}{2} g_{s,22}^{d,0}(z) = 3 g_{s,22}^{d,0}(z) = \frac{1}{2} h_{s,22}^{d,0}(z) = - \sqrt{1 - 4 z} (1 + 2z),$$

$$\frac{1}{3} g_{s,31}^{d,0}(z) = \frac{1}{2} g_{s,32}^{d,0}(z) = 3 g_{s,32}^{d,0}(z) = \frac{1}{2} h_{s,32}^{d,0}(z) = \frac{2}{\sqrt{1 - 4 z}} [1 - 2z (1 + z)],$$

$$\frac{1}{3} g_{s,41}^{d,0}(z) = \frac{1}{2} g_{s,42}^{d,0}(z) = 3 g_{s,42}^{d,0}(z) = \frac{1}{2} h_{s,42}^{d,0}(z) = \frac{2}{\sqrt{1 - 4 z}},$$

$$6 g_{s,31}^{u,0}(z) = g_{s,12}^{u,0}(z) = 6 g_{s,32}^{u,0}(z) = h_{s,11}^{u,0}(z) = h_{s,32}^{u,0}(z) = 12 (1 - z) (1 + z),$$

$$h_{s,11}^{d,0} = h_{s,12}^{d,0} = h_{s,11}^{u,0} = h_{s,12}^{u,0} = 0,$n

$$g_{s,11}^{u,0} = g_{s,12}^{u,0} = g_{s,22}^{u,0} = h_{s,11}^{u,0} = h_{s,22}^{u,0} = h_{s,32}^{u,0} = 0.$$  \tag{B3}

The coefficients $g_{i,1j}^{d,0}$ are identical to $g_{i,1j}^{d,0}$ because of the symmetry under interchange of the masses in the loops, and $g_{i,1j}^{d,0}$ and $g_{i,1j}^{d,0}$ follow by setting $z = 0$ in $g_{i,1j}^{d,0}$ and $g_{i,1j}^{d,0}$ respectively. As with the dimension-6 operators, the coefficients of the weak annihilation in $D_1$ with quarks in the loop are identical to those of the weak annihilation in $D_0$ when we interchange $C_1$ and $C_2$. For the semileptonic weak annihilation, we obtain

$$g_{11}^{\tau,0}(z) = -(1 - z)^2 (1 + 2z),$$

$$g_{12}^{\tau,0}(z) = -(1 - z)^2 (1 + 2z),$$

$$g_{13}^{\tau,0}(z) = 2 (1 - z) (1 + z + z^2),$$

$$g_{14}^{\tau,0}(z) = - 12 z^2 (1 - z),$$

$$h_{11}^{\tau,0}(z) = 0.$$  \tag{B4}

where $z = m_c^2 / m_b^2$ and the $g_{i,1j}^{d,0}$ are given by setting $z = 0$. The additional coefficients that arise when we use HQET operators are given by the relation

$$(s_{ij}^{q,0})_{\text{HQET}} = (F_{ij}^{q,0})_{\text{QCD}},$$

$$(s_{ij}^{q,0})_{\text{HQET}} = (F_{ij}^{q,0})_{\text{QCD}},$$

$$(h_{ij}^{q,0})_{\text{HQET}} = (G_{ij}^{q,0})_{\text{QCD}},$$

$$(h_{ij}^{q,0})_{\text{HQET}} = (G_{ij}^{q,0})_{\text{QCD}}.$$  \tag{B5}

**APPENDIX C: PARAMETRIZATION OF THE MATRIX ELEMENTS**

We parametrize the matrix elements of the dimension-6 QCD operators following Ref. [23]:

$$\langle D^+ | Q_d - Q_u | D^+ \rangle = f_D^4 M_D \langle T^d - T^u | B_1 \rangle, \tag{C1}$$

$$\langle D^+ | Q_s^t - Q_s^u | D^+ \rangle = f_D^4 M_D \langle T^s - T^s | B_2 \rangle, \tag{C1}$$

$$\langle D^+ | T_d^u - T_u d^+ | D^+ \rangle = f_D^4 M_D \langle T_d^u - T_u d^+ | e_1 \rangle, \tag{C1}$$

$$\langle D^+ | T_s^u - T_s^s d^+ | D^+ \rangle = f_D^4 M_D \langle T_s^u - T_s^s d^+ | e_2 \rangle. \tag{C1}$$
For $q = u, d$, the dimension-7 operators $P_3^q$, $P_2^q$, $S_1^q$, $S_2^q$ vanish identically if we neglect the up and down quark masses. The operators $P_3^q$, $P_4^q$, $S_1^q$, $S_2^q$ do not arise in QCD. We choose the following parametrization for the remaining ones:

\[
\begin{align*}
\langle D^+ | P_3^q - P_3^q | D^+ \rangle &= -\frac{f_3^2 M_D M_D - m_c}{2 m_c} \rho_3 + \mathcal{O}(1/m_c^2), \\
\langle D^+ | S_3^q - S_3^q | D^+ \rangle &= -\frac{f_3^2 M_D M_D - m_c}{2 m_c} \sigma_3 + \mathcal{O}(1/m_c^2), \\
\langle D^+ | F_4^q - F_4^q | D^+ \rangle &= -\frac{f_4^2 M_D M_D - m_c}{2 m_c} \rho_4 + \mathcal{O}(1/m_c^2), \\
\langle D^+ | S_4^q - S_4^q | D^+ \rangle &= -\frac{f_4^2 M_D M_D - m_c}{2 m_c} \sigma_4 + \mathcal{O}(1/m_c^2). \\
\end{align*}
\]  

(C2)

This parametrization is inspired by the vacuum saturation approximation (VSA), where $B_1 = 1, B_2 = 1 + 2(M_D - m_c)/m_c + \mathcal{O}(1/m_c^2)$, and $\epsilon_1 = \epsilon_2 = 0$ for dimension six, and $\rho_3 = \rho_4 = 1$ and $\sigma_3 = \sigma_4 = 0$ for dimension seven.

For HQET operators, we use a parametrization following Ref. [43], where the contributions of valence and nonvalence operators are distinguished explicitly. We parametrize the matrix elements of the nonvalence operators ($q \neq q'$) by

\[
\begin{align*}
\langle D_q | Q_q^q | D_q \rangle &= \frac{f_3^2 M_D}{2 m_c} \delta_1^{qq'}, \\
\langle D_q | Q_S^q | D_q \rangle &= \frac{f_3^2 M_D}{2 m_c} \delta_2^{qq'}, \\
\langle D_q | T_q^q | D_q \rangle &= \frac{f_3^2 M_D}{2 m_c} \delta_3^{qq'}, \\
\langle D_q | T_S^q | D_q \rangle &= \frac{f_3^2 M_D}{2 m_c} \delta_4^{qq'}, \\
\end{align*}
\]  

(C3)

and the matrix elements of the valence operators ($q = q'$) by

\[
\begin{align*}
\langle D_q | Q_i^q | D_q \rangle &= \frac{f_3^2 M_D}{2 m_c} (B_i^q + \delta_1^{qq}), \\
\langle D_q | Q_S^q | D_q \rangle &= \frac{f_3^2 M_D}{2 m_c} (B_2^q + \delta_2^{qq}), \\
\langle D_q | T_i^q | D_q \rangle &= \frac{f_3^2 M_D}{2 m_c} (\epsilon_i^q + \delta_3^{qq}), \\
\langle D_q | T_S^q | D_q \rangle &= \frac{f_3^2 M_D}{2 m_c} (\epsilon_2^q + \delta_4^{qq}). \\
\end{align*}
\]  

(C4)

In the VSA, we find $B_1^q = B_2^q = 1$, while the $\epsilon_i^q, \epsilon_2^q$, and all the $\delta$'s vanish. We proceed in the same way for the dimension-7 matrix elements of nonvalence operators

\[
\begin{align*}
\langle D_q | P_i^q | D_q \rangle &= -\frac{f_3^2 M_D}{2 m_c} m_q \delta_{\rho, i}, \\
\langle D_q | P_i^{qq'} | D_q \rangle &= -\frac{f_3^2 M_D}{2 m_c} m_q m_{q'} \delta_{\rho, i}, \\
\end{align*}
\]  

(C5)

and valence operators

\[
\begin{align*}
\langle D_q | P_i^q | D_q \rangle &= -\frac{f_3^2 M_D}{2 m_c} (\rho_i^q + \delta_{\rho, i}), \\
\langle D_q | P_i^{qq'} | D_q \rangle &= -\frac{f_3^2 M_D}{2 m_c} (\rho_i^q + \delta_{\rho, i}), \\
\end{align*}
\]  

(C6)

The color octet operators are parametrized by Eqs. (C5) and (C6) with the replacements $P \rightarrow S$ and $\rho \rightarrow \sigma$. This is chosen such that in the vacuum insertion $\rho_i^q = 1$, and all the $\sigma$'s and $\delta$'s vanish.
