Abstract

We prove an a-posteriori error estimate for \( hp \)-adaptive discontinuous Galerkin methods for the numerical solution of convection-diffusion equations on anisotropically refined rectangular elements. The estimate yields global upper and lower bounds of the errors measured in terms of a natural norm associated with diffusion and a semi-norm associated with convection. The anisotropy of the underlying meshes is incorporated in the upper bound through an alignment measure. We present a series of numerical experiments to test the feasibility of this approach within a fully automated \( hp \)-adaptive refinement algorithm.

Keywords: discontinuous Galerkin methods, error estimation, \( hp \)-adaptivity, convection-diffusion problems

1. Introduction

We derive and numerically test a residual-based a-posteriori error estimate for \( hp \)-version discontinuous Galerkin (DG) methods for the convection-diffusion model problem:

\[-\varepsilon \Delta u + a(x) \cdot \nabla u = f(x) \quad \text{in} \; \Omega, \]
\[u = 0 \quad \text{on} \; \Gamma.\] (1)

Here, \( \Omega \) is a bounded Lipschitz polygonal domain in \( \mathbb{R}^2 \) with boundary \( \Gamma = \partial \Omega \). The parameter \( \varepsilon > 0 \) is the (constant) diffusion coefficient, the function \( a(x) \in W^{1,\infty}(\Omega)^2 \) a
given flow field, and \( f(x) \) a source term in \( L^2(\Omega) \). We assume that

\[
\nabla \cdot a = 0 \quad \text{in} \; \Omega.
\]

For simplicity, we shall also assume that \( \|a\|_{L^\infty(\Omega)} \) and the length scale of \( \Omega \) are of order one so that \( \varepsilon^{-1} \) is the Péclet number of the problem. The standard weak form of the convection-diffusion equation (1) is to find \( u \in H^1_0(\Omega) \) such that

\[
A(u, v) = \int_\Omega \left( \varepsilon \nabla u \cdot \nabla v + a \cdot \nabla uv \right) \, dx = \int_\Omega f v \, dx \quad \forall \, v \in H^1_0(\Omega).
\]

Under assumption (2), the variational problem (3) is uniquely solvable.

This paper is a continuation of our work on \( hp \)-adaptive DG methods for diffusion and convection-diffusion problems. This work was initiated in [1], where an energy norm \( \varepsilon \) -posteriori error estimate was derived for \( hp \)-version DG methods for diffusion problems in two dimensions. The key technical tool was the introduction of an \( hp \)-version averaging operator, inspired by that of [2] for \( h \)-version DG methods. In [3], related averaging techniques were used in the numerical analysis of continuous interior penalty \( hp \)-elements. Extensions to linear elasticity in mixed form, quasi-linear elliptic problems and three-dimensional diffusion equations were presented in [4], [5] and [6], respectively. In [7], the same averaging approach was pursued to derive an error estimator for \( hp \)-adaptive DG methods for convection-diffusion equations on isotropically refined meshes. This estimator has the distinct feature that it is robust in the Péclet number of the problem with respect to a suitably defined error measure (i.e., it is reliable and efficient with constants that are independent of the parameter \( \varepsilon \)).

The purpose of this paper is to extend the work [7] to anisotropically refined meshes, and to present an estimator \( \eta \) which yields global upper and lower bounds of the error measured in terms of a natural norm associated with diffusion and a semi-norm associated with convection. In particular, our error measure contains the standard DG energy norm and a variant of the dual norm introduced in [8] to measure convective effects. The constant in the lower bound is independent of \( \varepsilon \) and the mesh size, but weakly depending on the polynomial degrees, as in many \( hp \)-version error estimators for diffusion problems. In the upper bound, we use an alignment measure to incorporate the anisotropy of the underlying meshes in the reliability constant; see [9, 10, 11] and the references therein. As a consequence, the upper bound depends on the elemental aspect ratios and is not fully robust in the Péclet number, in contrast to the case of isotropic elements considered in [7]. Our analysis is valid for \( 1 \)-irregularly refined rectangular elements with arbitrarily large aspect ratios, and is based on the \( hp \)-version averaging operator of [7], but with anisotropically scaled approximation properties.

We present a series of numerical experiments to test the feasibility of this approach within a fully automated \( hp \)-adaptive algorithm. Our tests indicate that internal and boundary layers are correctly captured and resolved at exponential rates of convergence in the number of degrees of freedom. We further observe that as soon as a reasonable \( h \)-resolution of the layers is achieved, the alignment measure is of moderate size, and the ratios of the error estimators and the energy errors are practically independent of the diffusion parameter \( \varepsilon \) and the mesh size. In all the tests, our new \( hp \)-version anisotropic refinement strategy outperforms similar strategies based on isotropic mesh refinement by orders of magnitude.
Let us also point out that in [12, 13], a duality-based a-posteriori approach was successfully proposed and studied for $hp$-adaptive DG methods for convection-diffusion problems on anisotropically refined meshes and with anisotropically enriched elemental polynomial degrees.

The outline of the rest of the paper is as follows. In Section 2, we introduce $hp$-adaptive discontinuous Galerkin methods for the discretization of the convection-diffusion problem (1). In Section 3, we state and discuss our a-posteriori error estimates. The proof of these estimates is carried out in Section 4. In Section 5, we present a series of numerical tests illustrating the performance of a fully automated $hp$-adaptive algorithm. Finally, in Section 6, we end with some concluding remarks.

Throughout the paper, we shall frequently use the symbols $\lesssim$ and $\gtrsim$ to denote bounds that are valid up to positive constants, independently of the local mesh sizes, the elemental aspect ratios, the elemental polynomial degrees, and the parameter $\epsilon$.

2. Interior penalty discretization

In this section, we introduce an $hp$-version interior penalty DG finite element method for the discretization of equation (1) on anisotropically refined meshes.

2.1. Elements and meshes

We consider (a family of) partitions $T$ of $\Omega$ into disjoint rectangular elements \{K\}. Each element is the image of the reference square $\hat{K} = (-1, 1)^2$ under an affine elemental mapping $F_K$. We allow for 1-irregularly refined meshes, where each elemental edge may contain at most one hanging node located in the middle of the edge. For each rectangle $K \in T$, we denote by $\Sigma^1_1$ and $\Sigma^1_2$ its two anisotropic directions, as shown in Figure 1. With the direction vectors, we associate the matrix

$$M_K = [\Sigma^1_1, \Sigma^1_2].$$

The lengths of the direction vectors are denoted by $h^1_K$ and $h^2_K$, respectively. Then we define the minimum and maximum diameter of an element $K$ by

$$h_{\text{min},K} = \min\{h^1_K, h^2_K\}, \quad h_{\text{max},K} = \max\{h^1_K, h^2_K\}.$$  

We denote by $\mathcal{N}(K)$ the set of the four vertices of $K$, and define $\mathcal{N}(T) = \cup_{K \in T} \mathcal{N}(K)$. We further split the set of all nodes into interior nodes and boundary nodes, that is, we
write $N(T) = N_I(T) \cup N_B(T)$. We denote by $E(K)$ the set of the four elemental edges of an element $K$. The length of an elemental edge is denoted by $h_E$, i.e., $h_E = h^i_K$ if $E$ is parallel to $\nabla^i_K$, $i=1,2$.

The non-empty intersection $E = \partial K \cap \partial K'$ of two neighboring elements $K, K' \in T$ is called an interior edge of $T$. The set of all interior edges is denoted by $E_I(T)$. Analogously, the non-empty intersection $E = \partial K \cap \Gamma$ of an element $K \in T$ with the boundary $\Gamma$ is called a boundary edge of $T$. The set of all boundary edges of $T$ is denoted by $E_B(T)$. Moreover, we set $E(T) = E_I(T) \cup E_B(T)$.

Let now $E \in E(T)$ be part of an elemental edge of element $K$. Then we denote by $h^j_E, K$ the width of element $K$ perpendicular to $E$. That is, $h^j_E, K = h^{j-i}_K$ if $E$ is parallel to $\nabla^i_K$, $i=1,2$. We then make the following bounded local variation assumption: there is a constant $\rho_1 \geq 1$ independent of the particular mesh in the mesh family, such that

$$\rho_1^{-1} \leq h^j_E, K / h^{j-i}_E, K' \leq \rho_1,$$  \hfill (6)

for all edges $E \in E_I(T)$ shared by elements $K$ and $K'$. Moreover, for $E \in E(T)$ we define

$$h^j_E = \begin{cases} \min\{h^j_E, K, h^{j-i}_E, K'\}, & E \in E_I(T), E = \partial K \cap \partial K', \\ h^{j-i}_E, K, & E \in E_B(T), E = \partial K \cap \Gamma, \end{cases}$$ \hfill (7)

and

$$h_{\min, E} = \begin{cases} \min\{h_{\min, K}, h_{\min, K'}\}, & E \in E_I(T), E = \partial K \cap \partial K', \\ h_{\min, K}, & E \in E_B(T), E = \partial K \cap \Gamma. \end{cases}$$ \hfill (8)

Remark 1. Assumption (6) and the fact that the meshes are 1-irregular imply that there is a constant $C \geq 1$ independent of the particular mesh in the mesh family, such that

$$C^{-1} \leq h^j_E / h^{j-i}_E, K \leq C, \quad C^{-1} \leq h_{\min, E} / h_{\min, K} \leq C, \quad \hfill (9)$$

for any edge $E$ which is part of an elemental edge of $K$.

2.2. Polynomial degrees and finite element spaces

With each element $K \in T$, we associate a polynomial degree $p_K \geq 1$. We store these degrees in the vector $p = \{p_K : K \in T\}$, and set $|p| = \max_{K \in T} p_K$. We assume that $p$ is also of bounded local variation: there is a second constant $\rho_2 \geq 1$ independent of the particular mesh in the mesh family, such that

$$\rho_2^{-1} \leq p_K / p_{K'} \leq \rho_2,$$ \hfill (10)

for any pairs of neighboring elements $K, K' \in T$. For $E \in E(T)$, we introduce the edge polynomial degree $p_E$ by

$$p_E = \begin{cases} \max\{p_K, p_{K'}\}, & E = \partial K \cap \partial K' \in E_I(T), \\ p_K, & E = \partial K \cap \Gamma \in E_B(T). \end{cases}$$ \hfill (11)

The $hp$-version discontinuous Galerkin finite element space is now given by

$$S_p(T) = \left\{ v \in L^2(\Omega) : v|_K \circ F_K \in Q_{p_K}(\hat{K}), K \in T \right\},$$

with $Q_{p_K}(\hat{K})$ denoting the set of all polynomials on the reference square $\hat{K}$ of degree at most $p_K$ in each coordinate direction.
2.3. Discretization

We consider the following discontinuous Galerkin method for the approximation of the convection-diffusion problem (1): Find $u_{hp} \in S_p(T)$ such that

$$A_{hp}(u_{hp}, v) = \int_{\Omega} f v \, dx$$

for all $v \in S_p(T)$, with the bilinear form $A_{hp}$ given by

$$A_{hp}(u, v) = \sum_{K \in T} \int_K (\varepsilon \nabla u \cdot \nabla v + \mathbf{a} \cdot \nabla uv) \, dx$$

$$- \sum_{E \in \mathcal{E}(T)} \int_E \frac{\varepsilon}{h_E} \jump{u} \cdot \jump{v} \, ds - \sum_{E \in \mathcal{E}(T)} \int_E \jump{\nabla v} : \jump{u} \, ds$$

$$+ \sum_{E \in \mathcal{E}(T)} \int_E \gamma \frac{p_E}{h_E} \jump{u} \cdot \jump{v} \, ds - \sum_{K \in T} \int_{\partial K \cap \Gamma_{in}} \mathbf{a} \cdot \mathbf{n}_K \, uv \, ds$$

$$+ \sum_{K \in T} \int_{\partial K \cap \Gamma_{out}} \mathbf{a} \cdot \mathbf{n}_K (u^e - u) v \, ds.$$

Here, the operators $\jump{\cdot}$ and $\jump{\cdot}$ denote the usual averages and jumps of piecewise smooth functions across edges of $T$; see [7, Section 2.2] for their explicit definitions. Note that for a piecewise smooth function, the operator $\nabla$ has to be understood as the broken gradient. Furthermore, we denote by $u^e$ the trace of $u$ on an elemental boundary taken from the exterior, and by $\Gamma_{in}$ and $\partial K_{in}$ the inflow parts of $\Gamma$ and $K \in T$, respectively:

$$\Gamma_{in} = \{ x \in \Gamma : \mathbf{a}(x) \cdot \mathbf{n}(x) < 0 \}, \quad \partial K_{in} = \{ x \in \partial K : \mathbf{a}(x) \cdot \mathbf{n}_K(x) < 0 \}.$$

Finally, the constant $\gamma > 0$ is the interior penalty parameter.

The variational problem (12) is uniquely solvable, provided that the parameter $\gamma$ is chosen sufficiently large, independently of the local mesh sizes, the elemental aspect ratios, the elemental polynomial degrees, and the parameter $\varepsilon$; see, e.g., [7, 14, 15] and the references therein.

3. A-posteriori error estimates

In this section, our main results are presented and discussed.

3.1. Norms

We begin by introducing the standard energy norm associated with the discontinuous Galerkin discretization of the diffusion term:

$$\|v\|_{E,T}^2 = \sum_{K \in T} \varepsilon \|\nabla v\|_{L^2(K)}^2 + \text{jump}_{p,T}(v)^2,$$

$$\text{jump}_{p,T}(v)^2 = \sum_{E \in \mathcal{E}(T)} \varepsilon \frac{p_E}{h_E} \|\jump{v}\|_{L^2(E)}^2.$$
Under assumption (2) and for $\gamma$ sufficiently large, the DG form $A_{hp}$ is coercive over the finite element space $S_p(T)$ with respect to the energy norm.

To measure the effects of convection, we use a variant of the dual norm introduced in [8], namely the following semi-norm

$$|v|_* = \sup_{w \in H_0^1(\Omega) \setminus \{0\}} \frac{\int_{\Omega} (qv) \cdot \nabla w \, dx}{\|w\|_{E,T}}.$$  \hfill (14)

In the sequel, we shall refer to $|\cdot|_*$ as the convective semi-norm. Note that since $\|a\|_{L^\infty(\Omega)}$ is assumed to be of order one, we have

$$|v|_* \lesssim \varepsilon^{-1/2} \|v\|_{L^2(\Omega)}. \hfill (15)$$

Finally, we shall introduce the following semi-norm involving the inter-elemental jumps:

$$o\text{jump}_{p,T}(v)^2 = \sum_{E \in \mathcal{E}(T)} \left( \frac{\varepsilon \gamma p E h_E^2}{h_{\text{min},E}^2} + \frac{h_E}{\varepsilon p E} \right) \| [v] \|_{L^2(E)}^2. \hfill (16)$$

In (16), the expressions weighting the $L^2$-norms of the jumps are related to diffusion and convection as well. Indeed, the weights $\varepsilon \gamma p^2 h_E^4 h_{\text{min},E}^{-2}$ are needed to account for the anisotropy of the meshes with respect to diffusive terms; they are motivated by the scaling properties of the averaging operator in Theorem 12. In the case of isotropic elements, they coincide with the weights in (13) (up to the interior penalty parameter $\gamma$); see also [7]. On the other hand, the weights $\varepsilon^{-1} p^{-1} h_E^2$ represent cell Péclet numbers in direction perpendicular to $E$, and are associated with convection.

In what follows, it will be convenient to define

$$|v|_{O,T}^2 = |v|^2_* + o\text{jump}_{p,T}(v)^2. \hfill (17)$$

In addition to the standard energy norm (13), we shall use the semi-norm (17) as part of our error measure.

3.2. Error estimators and data approximation

Let now $u_{hp} \in S_p(T)$ be the discontinuous Galerkin approximation obtained by (12). Moreover, let $f_{hp}$ and $g_{hp}$ denote piece polynomial approximations in $S_p(T)$ and $S_p(T)^2$ to the right-hand side $f$ and the flow field $g$, respectively. For example, these approximations can be taken as $L^2$-projections into $S_p(T)$ and $S_p(T)^2$.

For each element $K \in \mathcal{T}$, we then introduce a local error indicator $\eta_K$, which is given by the sum of the three terms

$$\eta_K^2 = \eta_{R_K}^2 + \eta_{E_K}^2 + \eta_{J_K}^2. \hfill (18)$$

The first term $\eta_{R_K}$ is the interior residual defined by

$$\eta_{R_K}^2 = \varepsilon^{-1} p_K^{-2} h_{\text{min},K}^2 \| f_{hp} + \varepsilon \Delta u_{hp} - g_{hp} \cdot \nabla u_{hp} \|_{L^2(K)}. \hfill (19)$$
The second term $\eta_{EK}$ is the edge residual given by
\[
\eta_{EK}^2 = \frac{1}{2} \sum_{E \in \mathcal{E}(K)} \frac{h_{\min,K}^2}{\varepsilon_p h_{E,K}^2} \| \varepsilon \nabla u_{hp} \|_{L^2(E \setminus \Gamma)}^2.
\] (20)

The last residual $\eta_{JK}$ measures the error in the jumps of the approximate solution $u_{hp}$:
\[
\eta_{JK}^2 = \frac{1}{2} \sum_{E \in \mathcal{E}(K)} \left( \frac{\varepsilon h_{E,K}^2}{h_{\min,K}^2} + \frac{h_{E,K}^2}{\varepsilon_p h_{E,K}^2} \right) \left( \| u_{hp} \|_{L^2(E \setminus \Gamma)}^2 + \| \nabla u_{hp} \|_{L^2(K)}^2 \right),
\] (21)

Note that the residual $\eta_{JK}$ contains the usual diffusive jumps as in (13) (but weighted with $h_{E,K}^2$ rather than $h_{\min,K}^2$ as in [5, 7]), along with the additional jump terms appearing in (16).

We also introduce the local data approximation term
\[
\Theta_{K}^2 = \varepsilon^{-1} h_{E,K}^{-2} h_{\min,K}^2 \left( \| f - f_{hp} \|_{L^2(K)}^2 + \| (a - a_{hp}) \cdot \nabla u_{hp} \|_{L^2(K)}^2 \right),
\]
and define our (global) error estimator and data approximation term by
\[
\eta^2 = \sum_{K \in T} \eta_{K}^2, \quad \Theta^2 = \sum_{K \in T} \Theta_{K}^2.
\] (22)

3.3. A-posteriori estimates

The error estimator $\eta$ in (22) is reliable up to a so-called alignment measure $\mathcal{M}(v, T)$. This notion was originally introduced in [10]; see also [9, 11].

Definition 2. Let $v \in H^1(\Omega)$ be an arbitrary non-constant function and $T$ a triangulation of $\Omega$. The alignment measure $\mathcal{M}(v, T)$ is then defined by
\[
\mathcal{M}(v, T) = \left( \sum_{K \in T} h_{\min,K}^{-2} \| \nabla v \|_{L^2(K)}^2 \right)^{1/2} / \| \nabla v \|_{L^2(\Omega)}.
\]

The expression $\mathcal{M}(v, T)$ measures how well the possibly anisotropic function $v$ is aligned with the mesh $T$. It also appears naturally in anisotropic interpolation estimates. We note that
\[
1 \leq \mathcal{M}(v, T) \lesssim \max_{K \in T} \frac{h_{\max,K}}{h_{\min,K}} \forall v \in H^1(\Omega).
\]
Hence, for isotropic meshes the alignment measure is always of order one.

We are now ready to state our upper bound.

Theorem 3. Let $u$ be the solution of (1) and $u_{hp} \in S_p(T)$ its DG approximation obtained by (12). Let the error estimator $\eta$ and the data approximation error $\Theta$ be defined by (22). Then we have the a-posteriori error bound
\[
\| u - u_{hp} \|_{E,T} + |u - u_{hp}|_{O,T} \lesssim \mathcal{M}(v, T) (\eta + \Theta).
\] (23)
Here, $v \in H^1_0(\Omega)$ is the test function defined in the inf-sup condition (33) below.
Remark 4. We emphasize that the function $v \in H^1_0(\Omega)$ appearing in $M(v, T)$ in the bound (23) is not the solution of problem (1). Instead, it is a test function related to the conforming part of the error, analogously to the analysis of [10] for the Poisson problem. As such, it is not possible to easily estimate or evaluate $M(v, T)$ in a more explicit manner. However, we observe numerically that $M(v, T)$ becomes of moderate size once anisotropic solution behavior is sufficiently well resolved. For additional discussions on the alignment measure, we refer the reader to [10, 11] and the references therein.

Remark 5. Note that estimate (23) does not provide an upper bound for the $L^2$-errors. However, estimate (15) implies that

$$\|u - u_{hp}\|_\star \lesssim \varepsilon^{-1/2} \|u - u_{hp}\|_{L^2(\Omega)}.$$

Our numerical experiments indicate that the estimators $\eta$ overestimate this weighted $L^2$-errors (and thus the $L^2$-errors for small $\varepsilon$) for sufficiently well resolved layers. They also confirm that the standard $L^2$-errors converge exponentially, with convergence plots that are qualitatively very similar to those in the energy errors; see Section 5.

The proof of Theorem 3 is presented in Section 4. It is based on using an $hp$-version anisotropic averaging operator as in [7] and a uniform inf-sup condition as in [8] (see Lemma 7).

Our next theorem states a lower bound.

Theorem 6. Let $u$ be the solution of (1) and $u_{hp} \in S_p(T)$ its DG approximation obtained by (12). Let the error estimator $\eta$ and the data approximation error $\Theta$ be defined by (22). Then for any $\delta \in (0, \frac{1}{2})$, we have the bound

$$\eta \lesssim |p|^{d+1} \|u - u_{hp}\|_{E,T} + |p|^{2\delta + 1} \|u - u_{hp}\|_{O,T} + |p|^{2\delta + \frac{1}{2}} \Theta.$$

As in [1, 6, 7, 16], the efficiency bound in Theorem 6 is suboptimal with respect to the polynomial degree due to the use of inverse estimates (which are suboptimal in the polynomial order). The proof of Theorem 6 follows along the same lines, taking into account anisotropic scaling. For the sake of brevity, we omit it, and instead refer to [7] and [17, Section 5.4] for details.

4. Proofs

In this section, we present the proof of Theorem 3.

4.1. Stability

The following uniform inf-sup condition for the form $A$ is the crucial stability result in our analysis; it holds with an absolute constant.

Lemma 7. Assume (2). Then we have

$$\inf_{u \in H^1_0(\Omega) \setminus \{0\}} \sup_{v \in H^1_0(\Omega) \setminus \{0\}} \frac{A(u,v)}{\|u\|_{E,T} + \|v\|_\star} \geq \frac{1}{3}.$$

For the proof, we refer to [18, Lemma 4.4]; see also [8].
4.2. Auxiliary forms

Next, we split the discontinuous Galerkin form $A_{hp}$ into two parts, and define

\[
\tilde{A}_{hp}(u, v) = \sum_{K \in T} \int_K (\varepsilon \nabla u \cdot \nabla v + a \cdot \nabla uv) \, dx + \sum_{E \in E(T)} \int_E \frac{\varepsilon \gamma_E^2}{h_E} [u] \cdot [v] \, ds \\
- \sum_{K \in T} \int_{\partial K \cap \Gamma} a \cdot n_K uv \, ds + \sum_{K \in T} \int_{\partial K \setminus \Gamma} a \cdot n_K (u^e - u) v \, ds,
\]

\[
K_{hp}(u, v) = -\sum_{E \in E(T)} \int_E \langle \varepsilon \nabla u \rangle \cdot [v] \, ds - \sum_{E \in E(T)} \int_E \langle \varepsilon \nabla v \rangle \cdot [u] \, ds.
\]

We shall use these auxiliary forms to express both the continuous form $A$ in (3) and the discontinuous Galerkin form $A_{hp}$ in (12). Indeed, we have

\[
A(u, v) = \tilde{A}_{hp}(u, v), \quad u, v \in H_0^1(\Omega),
\]

\[
A_{hp}(u, v) = \tilde{A}_{hp}(u, v) + K_{hp}(u, v), \quad u, v \in S_p(T).
\]

4.3. Anisotropic interpolation

We will need the following anisotropic interpolation bounds.

**Lemma 8.** For $v \in H_0^1(\Omega)$, there exists a function $v_{hp} \in S_p(T)$ such that

\[
p_E^2 \|v - v_{hp}\|_{L^2(K)}^2 \lesssim \|M_K \nabla v\|_{L^2(K)}^2,
\]

\[
\|M_K \nabla (v - v_{hp})\|_{L^2(K)}^2 \lesssim \|M_K \nabla v\|_{L^2(K)}^2,
\]

\[
\sum_{E \in E(K)} h_{E,K}^p_E \|v - v_{hp}\|_{L^2(E)}^2 \lesssim \|M_K \nabla v\|_{L^2(K)}^2,
\]

for any $K \in T$.

**Proof.** The first two inequalities follow from those in [5, Lemma 3.7] and anisotropic scaling. Next, consider an elemental edge $E$ of $K$. By using the anisotropically scaled multiplicative trace inequality,

\[
\|v - v_{hp}\|_{L^2(E)}^2 \lesssim \frac{1}{h_{E,K}^p} \|M_K \nabla (v - v_{hp})\|_{L^2(K)} \|v - v_{hp}\|_{L^2(K)} + \frac{1}{h_{E,K}^p} \|v - v_{hp}\|_{L^2(K)}^2,
\]

the weighted Cauchy-Schwarz inequality, the fact that $p_E \geq 1$ and the previous two estimates, we find that

\[
\|v - v_{hp}\|_{L^2(E)}^2 \lesssim \frac{1}{h_{E,K}^p} \|M_K \nabla (v - v_{hp})\|_{L^2(K)}^2 + \frac{p_E}{h_{E,K}^p} \|v - v_{hp}\|_{L^2(K)}^2,
\]

\[
\lesssim \frac{1}{h_{E,K}^p} \left( \|M_K \nabla v\|_{L^2(K)}^2 + \|M_K \nabla v\|_{L^2(K)}^2 \right),
\]

which shows the third inequality. \qed
From Lemma 8 and the definition of the alignment measure, we immediately obtain global interpolation bounds.

**Lemma 9.** For \( v \in H^1_0(\Omega) \), there exists a function \( v_{hp} \in S_p(T) \) such that

\[
\sum_{K \in T} \frac{p_K^2}{h_{\text{min},K}^2} \|v - v_{hp}\|^2_{L^2(K)} \lesssim M(v, T)^2 \|\nabla v\|^2_{L^2(\Omega)},
\]

\[
\sum_{K \in T} \sum_{E \in \mathcal{E}(K)} \frac{h_{\text{per},E}^2}{h_{\text{min},K}^2} \|v - v_{hp}\|^2_{L^2(E)} \lesssim M(v, T)^2 \|\nabla v\|^2_{L^2(\Omega)}.
\] (27)

4.4. Averaging

We refer to averaging as the approximation of a discontinuous finite element function by a continuous one. This can be achieved by assigning to each conforming degree of freedom the value obtained by averaging over all the values of the discontinuous function taken elementwise at the corresponding degree of freedom. This procedure affects in particular vertex and edge degrees of freedom, but not interior ones. While averaging is relatively straightforward for conforming meshes, see also [1], it introduces some technicalities when dealing with hanging nodes.

Here, we shall make use of the averaging operator constructed and analyzed in [7], but scaled anisotropically. To handle 1-irregular meshes, it involves an auxiliary 1-irregular mesh \( \tilde{T} \) of rectangles, obtained from \( T \) as follows.

Let \( K \in T \). If all four elemental edges are edges of the mesh \( T \), that is, if \( \mathcal{E}(K) \subseteq \mathcal{E}(T) \), we leave \( K \) untouched. Otherwise, at least one of the elemental edges of \( K \), say \( E \), contains hanging nodes. In this case, we replace \( K \) by the two or four rectangles obtained by bisecting the elemental edges of \( K \). This construction is illustrated in Figure 2. Clearly, the mesh \( \tilde{T} \) is a refinement of \( T \); it is also 1-irregular. We denote by \( \mathcal{R}(K) \) the elements in \( \tilde{T} \) that have been generated inside \( K \in T \). If \( K \) has not been refined, then \( \mathcal{R}(K) = \{K\} \). Otherwise, the set \( \mathcal{R}(K) \) consists of two or four newly created elements.

![Figure 2: The construction of the auxiliary mesh \( \tilde{T} \) from \( T \).](image)

Then, we introduce the following auxiliary discontinuous Galerkin finite element space on the mesh \( \tilde{T} \):

\[
S_p(\tilde{T}) = \{ v \in L^2(\Omega) : v|_{\tilde{K}} \circ F_{\tilde{K}} \in Q_{p,K}(\tilde{K}), \tilde{K} \in \tilde{T} \},
\]
where the auxiliary polynomial degree vector \( \tilde{p} \) is defined by \( p_K = p_K \) for \( K \in \mathcal{R}(K) \). We have the inclusion \( S_{p}(T) \subseteq S_{\tilde{p}}(\tilde{T}) \). As in (13) and (17), we set

\[
\|v\|_{E,\tilde{T}}^2 = \sum_{K \in \tilde{T}} \varepsilon \|\nabla v\|_{L^2(K)}^2 + e\text{jump}_{p,\tilde{T}}(v)^2,
\]

\[
|v|_{O,\tilde{T}}^2 = |v|^2 + o\text{jump}_{p,\tilde{T}}(v)^2,
\]

where the jump weights are defined analogously to (7), (11), but with respect to the auxiliary mesh \( \tilde{T} \) and degree vector \( \tilde{p} \). Obviously, we have

\[
\|v\|_{E,T} = \|v\|_{E,\tilde{T}}, \quad |v|_{O,T} = |v|_{O,\tilde{T}},
\]

for all \( v \in H^1_0(\Omega) \). As in [7, Lemmas 4.2 and 4.3], the following results hold.

**Lemma 10.** Let \( v \in S_{p}(\tilde{T}) + H^1_0(\Omega) \) be such that \( [v]_E = [w]_E \) for all \( E \in \mathcal{E}(\tilde{T}) \), for a function \( w \in S_{p}(T) + H^1_0(\Omega) \). Then we have

\[
e\text{jump}_{p,T}(w) \lesssim e\text{jump}_{p,\tilde{T}}(v) \lesssim e\text{jump}_{p,T}(v),
\]

\[
o\text{jump}_{p,T}(w) \lesssim o\text{jump}_{p,\tilde{T}}(v) \lesssim o\text{jump}_{p,T}(v).
\]

**Lemma 11.** For \( v \in S_{p}(T) + H^1_0(\Omega) \), we have the bounds

\[
\|v\|_{E,T} \lesssim \|v\|_{E,\tilde{T}}, \quad |v|_{O,T} \lesssim |v|_{O,\tilde{T}}.
\]

Let \( S^*_p(\tilde{T}) \) be the conforming subspace of \( S_p(\tilde{T}) \) given by

\[
S^*_p(\tilde{T}) = S_p(\tilde{T}) \cap H^1_0(\Omega).
\]

We are now ready to state the following result regarding the averaging of a DG function. Due to the possible presence of hanging nodes, the averaged function will belong to the conforming space \( S^*_p(\tilde{T}) \) on the auxiliary mesh \( \tilde{T} \).

**Theorem 12.** There is an averaging operator \( I_{hp} : S_p(T) \to S^*_p(\tilde{T}) \) that satisfies

\[
\sum_{K \in \tilde{T}} \|v - I_{hp}v\|_{L^2(K)}^2 \lesssim \sum_{E \in \mathcal{E}(T)} \int_E (p_E)^{-2} h_{E}^2 \|v\|_{E}^2 \, ds,
\]

\[
\sum_{K \in \tilde{T}} \|\nabla(v - I_{hp}v)\|_{L^2(K)}^2 \lesssim \sum_{E \in \mathcal{E}(T)} \int_E p_E^2 h_{E}^2 h_{\text{min},E}^{-2} \|v\|_{E}^2 \, ds.
\]

The proof of Theorem 12 follows along the lines of [7, Section 5], but with the key Lemmas 5.3 and 5.4 there scaled anisotropically (which is readily achieved). For details, we refer to [17, Section 5.5].
4.5. Proof of Theorem 3

After these preliminary results, we now present the proof of Theorem 3. We follow [1, 18], and decompose the discontinuous Galerkin solution into a conforming part and a remainder:

\[ u_{hp} = u_{hp}^c + u_{hp}^r \quad \text{with} \quad u_{hp} = I_{hp} u_{hp} \in S_P^c(\tilde{T}) \subset H^1_0(\Omega), \]  

(31)

where \( I_{hp} \) is the averaging operator of Theorem 12. The remainder is then given by \( u_{hp}^r = u_{hp} - u_{hp}^c = u_{hp} - I_{hp} u_{hp} \in S_P^c(\tilde{T}) \). By Lemma 11 and the triangle inequality, we obtain

\[ \|u - u_{hp}\|_{E,T} + |u - u_{hp}|_{O,T} \lesssim \|u - u_{hp}\|_{E,\tilde{T}} + |u - u_{hp}|_{O,\tilde{T}} \]
\[ \lesssim \|u - u_{hp}^c\|_{E,\tilde{T}} + |u - u_{hp}^c|_{O,\tilde{T}} + \|u_{hp}^r\|_{E,\tilde{T}} + |u_{hp}^r|_{O,\tilde{T}} \]  

(32)

It is now sufficient to show that both the conforming part \( u - u_{hp}^c \) and the remainder \( u_{hp}^r \) can be bounded by the estimator \( \eta \) and the data approximation term \( \Theta \). We begin by bounding \( u_{hp}^r \).

**Lemma 13.** There holds

\[ \|u_{hp}^r\|_{E,\tilde{T}} + |u_{hp}^r|_{O,\tilde{T}} \lesssim \eta. \]

**Proof.** Since \( \|u_{hp}^r\|_E = \|u_{hp}\|_E \) for all \( E \in \mathcal{E}(\tilde{T}) \) and \( u_{hp} \in S_P(T) \), the definition of the jump residual \( \eta_{J_E} \) and Lemma 10 yield

\[ \|u_{hp}^r\|_{E,\tilde{T}} + |u_{hp}^r|_{O,\tilde{T}} \leq \sum_{K \in T} \varepsilon \|\nabla u_{hp}^c\|_{L^2(K)}^2 + |u_{hp}^c|_{L^2(K)}^2 + c J_{\min}(h_{\text{min}} E) \left( u_{hp}^c \right)^2 + c J_{\min}(h_{\text{min}} E) \left( u_{hp}^r \right)^2 \]
\[ \leq \sum_{K \in T} \varepsilon \|\nabla u_{hp}^c\|_{L^2(K)}^2 + |u_{hp}^c|_{L^2(K)}^2 + \sum_{K \in T} \eta_{J_K}^2. \]

Hence, only the volume terms and \( |u_{hp}^c|_*, \) need to be bounded further. Theorem 12 and the equivalences (9), (10) yield

\[ \varepsilon \sum_{K \in T} \|\nabla u_{hp}^c\|_{L^2(K)}^2 \lesssim \sum_{E \in \mathcal{E}(T)} \int_E \varepsilon h_{E}^{-1} h_{\text{min},E}^{-1} \|u_{hp}\|^2 \, ds \lesssim \sum_{K \in T} \eta_{J_K}^2. \]

To estimate \( |u_{hp}^c|_* \), we use the bound (15), Theorem 12, the fact that \( p E \geq 1 \), and the relations (9), (10). We obtain

\[ |u_{hp}^c|_* \leq \frac{1}{\varepsilon} \sum_{K \in T} \|u_{hp}^c\|_{L^2(K)}^2 \leq \frac{1}{\varepsilon} \sum_{E \in \mathcal{E}(T)} \left( h_{E} \right)^{-2} \|u_{hp}\|_{L^2(E)}^2 \lesssim \sum_{K \in T} \eta_{J_K}^2. \]

This finishes the proof. \( \Box \)

To bound the conforming errors in (32), we establish the following auxiliary result.
Lemma 14. For any \( v \in H^1_0(\Omega) \), we have
\[
\int_\Omega f(v - v_{hp}) dx - \tilde{A}_{hp}(u_{hp}, v - v_{hp}) + K_{hp}(u_{hp}, v_{hp}) \lesssim M(v, T) (\eta + \Theta) \| v \|_{E, T},
\]
where \( v_{hp} \in S_p(T) \) is the hp-interpolant of \( v \) in Lemma 8.

Proof. Integration by parts of the diffusive volume terms readily yields
\[
\int_\Omega f(v - v_{hp}) dx - \tilde{A}_{hp}(u_{hp}, v - v_{hp}) + K_{hp}(u_{hp}, v_{hp}) = T_1 + T_2 + T_3 + T_4 + T_5,
\]
where
\[
T_1 = \sum_{K \in T} \int_K (f + \varepsilon \Delta u_{hp} - \mathbf{a} \cdot \nabla u_{hp})(v - v_{hp}) dx,
\]
\[
T_2 = - \sum_{E \in \mathcal{E}(T)} \int_E \| \varepsilon \nabla u_{hp} \| \| v - v_{hp} \| ds,
\]
\[
T_3 = - \sum_{E \in \mathcal{E}(T)} \int_E \varepsilon \nabla u_{hp} \cdot [u_{hp}] ds,
\]
\[
T_4 = \sum_{K \in T \cap \partial K_m \setminus T} \int_{\partial K_m \cap \Gamma_m} \mathbf{a} \cdot \mathbf{n}_K (u_{hp} - u_{hp}^p) (v - v_{hp}) ds + \sum_{K \in T \cap \partial K_m \cap \Gamma_m} \int_{\partial K_m \cap \Gamma_m} \mathbf{a} \cdot \mathbf{n}_K u_{hp} (v - v_{hp}) ds,
\]
\[
T_5 = - \sum_{E \in \mathcal{E}(T)} \int_E \frac{\varepsilon \mathbf{p}_E^2}{h_E^2} [u_{hp}] \cdot [v - v_{hp}] ds.
\]
To bound \( T_1 \), we first add and subtract the data approximations. From the weighted Cauchy-Schwarz inequality and the approximation properties in (27), we obtain
\[
T_1 \lesssim M(v, T) \left( \sum_{K \in T} (\eta^2_{R_K} + \Theta^2_K) \right)^{\frac{1}{2}} \| v \|_{E, T}.
\]
Similarly, by the Cauchy-Schwarz inequality and (27), we have
\[
T_2 \lesssim \left( \sum_{K \in T \cap E \in \mathcal{E}(K)} \frac{h_{\text{min},K}^2}{\varepsilon p_E h_{E,K}^2} \| \varepsilon \nabla u_{hp} \|^2_{L^2(E \setminus T)} \right)^{\frac{1}{2}} \times \left( \sum_{K \in T \cap E \in \mathcal{E}(K)} \frac{\varepsilon p_E h_{E,K}^{\frac{1}{2}}}{h_{\text{min},K}^2} \| v - v_{hp} \|^2_{L^2(E)} \right)^{\frac{1}{2}} \lesssim M(v, T) \left( \sum_{K \in T} \eta^2_{E,K} \right)^{\frac{1}{2}} \| v \|_{E, T}.
\]
To estimate \( T_3 \), we employ the Cauchy-Schwarz inequality and the trace inequality in [3, Lemma 3.1]. This results in
\[
T_3 \lesssim \left( \sum_{E \in \mathcal{E}(T)} \frac{\varepsilon p_E^2}{h_E^2} \| u_{hp} \|^2_{L^2(E)} \right)^{\frac{1}{2}} \left( \sum_{K \in T \cap E \in \mathcal{E}(K)} \frac{\varepsilon h_{E,K}^{\frac{1}{2}}}{p_E} \| \nabla v_{hp} \|^2_{L^2(K)} \right)^{\frac{1}{2}} \lesssim \left( \sum_{K \in T} \eta^2_{J_K} \right)^{\frac{1}{2}} \left( \sum_{K \in T} \varepsilon \| \nabla v_{hp} \|^2_{L^2(K)} \right)^{\frac{1}{2}} \lesssim \left( \sum_{K \in T} \eta^2_{J_K} \right)^{\frac{1}{2}} \| v \|_{E, T}.
\]
For $T_4$, we use the boundedness of $\|a\|_{L^\infty(\Omega)}$, and apply again the Cauchy-Schwarz inequality and (27). We get

$$T_4 \lesssim \left( \sum_{K \in T} \sum_{E \in \mathcal{E}(K)} \frac{h_{\text{min},K}}{\varepsilon_p E E, K} \| u_{hp} \|^2_{L^2(E)} \right)^{\frac{1}{2}} \times \left( \sum_{K \in T} \sum_{E \in \mathcal{E}(K)} \frac{\varepsilon_p E E, K}{h_{\text{min},K}} \| v - v_{hp} \|^2_{L^2(E)} \right)^{\frac{1}{2}} \lesssim \mathcal{M}(v, T) \left( \sum_{K \in T} \frac{h_{\text{min},K}}{E_{\varepsilon_p E}} \| u_{hp} \|_{E, T} \right)^{\frac{1}{2}}.$$ 

Finally, we have

$$T_5 \lesssim \left( \sum_{K \in T} \sum_{E \in \mathcal{E}(K)} \frac{\varepsilon \gamma^2 h_{\text{min},K}}{(h_{E, K})^2} \| u_{hp} \|^2_{L^2(E)} \right)^{\frac{1}{2}} \times \left( \sum_{K \in T} \sum_{E \in \mathcal{E}(K)} \frac{\varepsilon_p E E, K}{h_{\text{min},K}} \| v - v_{hp} \|^2_{L^2(E)} \right)^{\frac{1}{2}} \lesssim \mathcal{M}(v, T) \left( \sum_{K \in T} \frac{h_{\text{min},K}}{E_{\varepsilon_p E}} \| u_{hp} \|_{E, T} \right)^{\frac{1}{2}}.$$ 

The above estimates for $T_1$ through $T_5$ yield the assertion. 

Now, we bound the norms of the conforming part $u - u_{hp}^c$ in (32).

**Lemma 15.** There holds:

$$\| u - u_{hp}^c \|_{E, T} + | u - u_{hp}^c |_{0, T} \lesssim \mathcal{M}(v, T)(\eta + \Theta).$$

**Proof.** Since $u - u_{hp}^c \in H_0^1(\Omega)$, we have $| u - u_{hp}^c |_{0, T} = | u - u_{hp}^c |^*$. The inf-sup condition in Lemma 7 ensures the existence of a test function $v \in H_0^1(\Omega)$ such that

$$\| u - u_{hp}^c \|_{E, T} + | u - u_{hp}^c |_{0, T} \lesssim A(u - u_{hp}^c, v) \quad \text{and} \quad \| v \|_{E, T} \leq 1. \quad (33)$$

Then, property (24) shows that

$$A(u - u_{hp}^c, v) = \int_{\Omega} f v dx - A_{hp}(u_{hp}^c, v) = \int_{\Omega} f v dx - \tilde{A}_{hp}(u_{hp}^c, v).$$

By employing the fact that $v \in H_0^1(\Omega)$ and integrating by parts the convection term, one finds that

$$\tilde{A}_{hp}(u_{hp}^c, v) = \tilde{A}_{hp}(u_{hp}, v) + R,$$

with

$$R = \sum_{K \in T} \int_{\mathcal{K}} (-\varepsilon \nabla u_{hp}^c + a u_{hp}^c) \cdot \nabla v \, dx.$$

From the DG method (12) and property (25), it follows that

$$\int_{\Omega} f v_{hp} \, dx = \tilde{A}_{hp}(u_{hp}, v_{hp}) + K_{hp}(u_{hp}, v_{hp}),$$

14
where \( v_{hp} \in S_p(T) \) is the \( hp \)-version interpolant of \( v \) in Lemma 8. Combining the above results yields

\[
A(u - u_{hp}^i, v) = \int_{\Omega} f(v - v_{hp}) \, dx - \tilde{A}_{hp}(u_{hp}, v - v_{hp}) + K_{hp}(u_{hp}, v_{hp}) - R.
\]

The estimate in Lemma 14 now shows that

\[
|A(u - u_{hp}^i, v)| \lesssim M(v, T) (\eta + \Theta) \|v\|_{E,T} + |R|.
\]

(34)

It remains to bound \(|R|\). From the Cauchy-Schwarz inequality, the definition of the convective semi-norm \(|\cdot|_\ast\), the conformity of \( v \) and Lemma 13, we conclude that

\[
|R| \lesssim \left( \|u_{hp}^i\|_{E,T} + |u_{hp}^i|_{O,T} \right) \|v\|_{E,T} \lesssim \eta \|v\|_{E,T}.
\]

(35)

Equations (33) through (35) imply the desired result.

The proof of Theorem 3 now is a consequence of inequality (32), Lemma 13 and Lemma 15.

5. Numerical experiments

We present a series of numerical examples where we use the error indicator \( \eta \) in (22) to drive a fully automated \( hp \)-adaptive refinement strategy. All computations are performed using the \texttt{AptoFEM} software package; see [21] for details. The resulting systems of linear equations are solved by exploiting the parallel multifrontal solver \texttt{MUMPS}; see [22, 23, 24], for example.

In our numerics below, we compare an anisotropic \( hp \)-adaptive scheme against an isotropic one, which is obtained by restricting the estimator \( \eta \) to isotropically refined meshes. In the isotropic case, we recall that Theorem 3 is valid without an alignment measure; cf. [7]. On the other hand, the adaptive resolution of boundary layers using isotropic refinement is generally much less robust and may be prohibitively expensive. In both schemes the meshes are adapted by marking the elements for refinement according to the size of the local error indicators \( \eta_K \); this is achieved by employing the fixed fraction strategy, see [25], with refinement fraction set to 25% and derefinement fraction to 10%. That is, the top 25% fraction of elements with the largest indicators \( \eta_K \) is marked for refinement, and the bottom 10% one with the smallest indicators for derefinement. For each marked element, the schemes automatically decide whether the local mesh size \( h_K \) or the local degree \( p_K \) should be adjusted accordingly. The choice to perform either \( h \)- or \( p \)-refinement is based on estimating the local smoothness of the (unknown) analytical solution. To this end, we employ the \( hp \)-adaptive strategy developed in [26], where the local regularity of the analytical solution is estimated from truncated local Legendre expansions of the computed numerical solution; see also [27, 28]. In the anisotropic \( hp \)-scheme, we also need to decide whether to perform isotropic or anisotropic \( h \)-refinement. To make this decision, we denote by \( E^1_K \), \( E^2_K \) the two sets containing the edges of \( K \) parallel to either \( e^{1}_K \) or \( e^{2}_K \), and then define

\[
\eta^i_{E^i_K} = \eta_{E^i_K}^1 + \eta_{J^i_K}^2, \quad i = 1, 2.
\]
Then the choice between isotropic or anisotropic $h$-refinement is made by comparing $\eta_E^k$ to $\eta_E^k$: if $\eta_E^k > 10 \eta_E^k$, then the element $K$ is refined anisotropically along the direction $\frac{\delta}{\delta_k}$. On the other hand, if $\eta_E^k > 10 \eta_E^k$, then the element $K$ is refined along the direction $\frac{\delta}{\delta_k}$. If none of the these two conditions is met, the element $K$ is refined isotropically. The derefinement procedure is the same for both schemes, and consists in simply undoing the last refinement made to the element.

In all our tests, we set the stabilization parameter to $\gamma = 10$. The approximate right-hand side $f_{hp}$ is taken as the $L^2$-projection of $f$ onto $S_p(\mathcal{T})$. The flow fields considered are constant or polynomial vector fields. Hence, the volume residuals $\eta_{E_K}$ can always be integrated exactly by taking $a_{hp} = a$. We then neglect the data approximation term $\Theta$ in (22).

5.1. Example 1

We take $\Omega = (0, 1)^2$, choose the constant convection $a = (1, 1)^T$, and select the right-hand side $f$ so that the solution to problem (1) is given by

$$u(x_1, x_2) = \left(\frac{e^{(x_1-1)/\epsilon} - 1}{e^{-1/\epsilon} - 1} + x_1 - 1\right)\left(\frac{e^{(x_2-1)/\epsilon} - 1}{e^{-1/\epsilon} - 1} + x_2 - 1\right).$$

The solution is analytic, but has boundary layers along the coordinate directions $x_1 = 1$ and $x_2 = 1$; their widths are both of order $O(\epsilon)$. This problem is well-suited to test whether the indicator $\eta$ is able to pick up the steep gradients near these boundaries using anisotropic refinement.

We test this problem for $\epsilon = 10^{-3}$, $\epsilon = 10^{-4}$ and $\epsilon = 10^{-6}$. For $\epsilon = 10^{-3}$, we begin the test with a uniform mesh of size $4 \times 4$ and the uniform polynomial degree $p_K = 2$, and for $\epsilon = 10^{-4}$, $\epsilon = 10^{-6}$, with an $8 \times 8$ mesh and $p_K = 2$. In Figure 3, we show the convergence of the estimators $\eta$, along with the energy norm errors $\|u - u_{hp}\|_{E,T}$, the weighted $L^2$-errors $\varepsilon^{-1/2}\|u - u_{hp}\|_{L^2(\Omega)}$ (which by Remark 5 bound the errors in the convective semi-norm $|u - u_{hp}|_*$), and the jump errors $\text{jump}_{hp}(u - u_{hp})$. We notice that the estimators provide upper bounds for the energy and jump errors, in agreement with Theorem 3. They also overestimate the weighted $L^2$-errors (which is not guaranteed by Theorem 3). On the basis of the a-priori analysis in [29] or [20, Section 3.4.6, page 118], we plot the errors against $N^{1/2}$, where $N$ is the number of degrees of freedom. In the asymptotic regime and in a semi-logarithmic scale, all the curves are roughly straight lines, indicating exponential convergence in $N^{1/2}$. We observe that the asymptotic regime is achieved once the layers are sufficiently well resolved.

In Figure 4, we compute the effectivity indices with respect to the DG energy norm errors, that is, the quantities $\eta/\|u - u_{hp}\|_{E,T}$. Again, note that the estimators $\eta$ actually bound a stronger norm; see Theorem 3. After a few iterations, the numerical values seem to settle in around 5, for all values of $\epsilon$ considered. This indicates that the alignment measure eventually becomes of moderate size once the layers are correctly captured. In this regime, the effectivity indices are relatively uniform in the number of iterations, similarly to a pure diffusion problem.

In Figure 5, we compare the DG energy norm errors obtained for the isotropic and anisotropic algorithms. Once the layers are properly captured, we expect exponential converge in both cases. However, resolving the layers is more costly for the isotropic scheme. Indeed, for $\epsilon = 10^{-3}$ and $\epsilon = 10^{-4}$, it can be seen that both methods converge

As discussed in Remark 5, our estimator does not control the $L^2$-norm errors. Nevertheless, the numerical results in Figure 6 indicate that the $L^2$-norm convergence is qualitatively very similar to the energy norm convergence depicted in Figure 5. As before, we observe exponential convergence rates, the anisotropic schemes yield much...
smaller errors than the isotropic ones, and the isotropic curve stagnates for \( \varepsilon = 10^{-6} \).

In Figure 6, we show the final adapted meshes for both schemes and for \( \varepsilon = 10^{-3} \). The colors indicate the order of polynomials used in each element; they are ranging between 2 and 11. In both cases, the adaptive procedure correctly captures the location and orientation of the boundary layers, and the meshes are refined accordingly. Particularly in the anisotropic case, we notice that relative large polynomial degrees are applied near the boundaries. This is consistent with the theoretical results in [29] or [20, Section 3.4.6, page 118]. Indeed, since the solution is analytic and once the layers are resolved, \( p \)-refinement is the most effective refinement strategy.

In Figure 8, we show the final anisotropically adapted mesh for \( \varepsilon = 10^{-4} \). Due to the presence of the strong layers, most of the adaptivity is performed very close to the right and upper boundaries of the domain. In order to better appreciate the adaptation of the mesh, we have magnified the region \((0.75, 1) \times (0.75, 1)\) in the upper-right corner of the domain. We observe strong anisotropic refinement along the layers. Qualitatively similar meshes are obtained for \( \varepsilon = 10^{-6} \).
5.2. Example 2

Next, we consider an example with an internal layer. In the domain $\Omega = (-1, 1)^2$, we take $a = (1, 1)^T$. We choose $f$ and the inhomogeneous Dirichlet boundary conditions such that the solution to (1) is given by

$$u(x_1, x_2) = \arctan\left(\frac{x_1}{\varepsilon}\right)(1 - x_2^2).$$

For small values of $\varepsilon$, the solution $u$ has an internal layer at $x_1 = 0$.

The estimator $\eta$ can be readily extended to take into account the inhomogeneous boundary conditions. We run this problem for $\varepsilon = 10^{-3}$ and $\varepsilon = 10^{-4}$. For $\varepsilon = 10^{-3}$, we begin the test with a uniform mesh of $4 \times 4$ and the uniform polynomial degree $p_K = 2$, and for $\varepsilon = 10^{-4}$, with a $16 \times 16$ mesh and $p_K = 2$.

We present the same plots as in Example 1. In Figure 9, we show the various error quantities. Again, we roughly see straight lines in a semi-logarithmic plot, indicating exponential convergence in $N^{1/2}$, although for $\varepsilon = 10^{-4}$ the convergence behavior particularly for the jump errors is much less clean. We observe that the estimator is overestimating the energy and jump errors, but not the weighted $L^2$-norm errors. This is not a contradiction to our theoretical results, since the $\varepsilon^{-1/2}$-weighted $L^2$-norm provides only an upper bound of the convective semi-norm of the errors; cf. Remark 5. The effectivity indices are depicted in Figure 10. Again, they start out large, but eventually converge to a reasonable value of around 5.

In Figures 11 and 12, we show the energy norm and $L^2$-norm errors for both the isotropic and anisotropic $hp$-algorithms. We can draw essential the same conclusions as in Example 1. The anisotropic version is clearly superior to the isotropic one; this is again more pronounced for the smaller value of $\varepsilon = 10^{-4}$. In this case, the isotropic $L^2$-error curve reaches a value of around $10^{-2}$ with over a million degrees of freedom, while the anisotropic plot decreases to the level of $10^{-10}$ using less than 360,000 degrees of freedom. Figure 13 shows the final adapted meshes for isotropic and anisotropic adaptivity for $\varepsilon = 10^{-3}$. Again, the final meshes are quite different, with the anisotropic one more effectively
adapted to the layers. Finally, in Figure 14 we show the final adapted anisotropic mesh for $\varepsilon = 10^{-4}$, as well as a zoom into the central region $(-0.25, 0.25) \times (-0.25, 0.25)$ to better visualize the anisotropically refined elements.

### 5.3. Example 3

Next, we consider a problem, where the wind is not aligned with the mesh. We take $\Omega = (-1, 1)^2$, $\mathbf{a} = (-\sin \frac{\pi}{6}, \cos \frac{\pi}{6})^T$, $f = 0$ and consider the boundary conditions $u = 0$ on $x_1 = -1$ and $x_2 = 1$, as well as

$$ u = \tanh \left( \frac{1 - x_2}{\varepsilon} \right) \text{ on } x_1 = 1, \quad u = \frac{1}{2} \left( \tanh \left( \frac{x_1}{\varepsilon} \right) + 1 \right) \text{ on } x_2 = -1. $$

The boundary data is almost discontinuous near the point $(0, -1)$, and causes $u$ to have an internal layer of width $O(\sqrt{\varepsilon})$ along the line $x_2 + \sqrt{3}x_1 = -1$, with values $u = 0$ to the left and $u = 1$ to the right, as well as a boundary layer along the outflow boundary. There is no exact solution available to this problem. We test this problem
Figure 11: Example 2: Comparison of the DG energy errors for isotropic and anisotropic refinement for
\( \varepsilon = 10^{-3} \) (left) and \( \varepsilon = 10^{-4} \) (right).

Figure 12: Example 2: Comparison of the \( L^2 \)-errors for isotropic and anisotropic refinement for \( \varepsilon = 10^{-3} \) (left) and \( \varepsilon = 10^{-4} \) (right).

with \( \varepsilon = 2.5 \times 10^{-4} \), and start the algorithm for \( p_K = 2 \) on a uniform mesh of 16 \times 16
elements.

In Figure 15, we plot the values of the error indicators \( \eta \) for the isotropic and
anisotropic \( hp \)-methods. We observe exponential convergence for the indicators in both
algorithms, with the curves being closer together than in the previous tests. The reason
for this is that in this example, the internal layer is not aligned with a coordinate direction. Hence, it cannot be anisotropically captured with the Cartesian meshes generated by our anisotropic code. As a result, the internal layer is only resolved isotropically, while anisotropic refinement is employed in the outflow layer. This is clearly visible in Figure 16, where we show the final anisotropically adapted mesh. In Figure 17 we show magnifications of the upper-left corner \((-1, -0.5) \times (0.5, 1)\) and the central region \((-0.5, 0) \times (-0.5, 0)\) of the adapted mesh. We note that designing fully automated ways to properly align meshes is a crucial aspect of anisotropic \( hp \)-adaptivity, which we do not address in this paper.
5.4. Example 4

Finally, we test our algorithm for an example with variable convection. In the square $\Omega = (-1, 1)^2$, we take the recirculating flow field $a = (2y(1 - x^2), -2x(1 - y^2))^T$, set $f = 0$, and impose the inhomogeneous boundary conditions

$$u = \tanh \left( \frac{1 - x_2}{\varepsilon} \right) \text{ on } x_1 = -1, \quad u = \tanh \left( \frac{1 - x_1}{\varepsilon} \right) \text{ on } x_2 = -1,$$

and $u = 0$ on $x_1 = 1$ and $x_2 = 1$. In this problem, all the boundaries are characteristic, and the nearly discontinuous boundary conditions introduce boundary layers near them. Again, there is no exact solution available. We test the example with $\varepsilon = 10^{-6}$, and start our $hp$-algorithm with a uniform mesh of $16 \times 16$ elements and the uniform degree $p_K = 2$. Since the convection field $a$ is polynomial, we have evaluated the residual $\eta_{RK}$ exactly.
by using a Gauss quadrature rule of sufficiently high order on each element $K$. Hence, we have $\omega_{hp} = \omega$ in our computations.

In Figure 18, we show the convergence of the estimators $\eta$ obtained for the isotropic and anisotropic schemes. Both plots start with rather large values, and it takes over 10 adaptive iterations until the layers are reasonably well resolved. After 16 iterations, the estimated errors are still relatively large. Nevertheless, the anisotropic algorithm reaches an estimated error value of roughly $10^{-1}$ with less than 90,000 degrees of freedom, whereas the isotropic error value still is of order one with $N = 250,000$. Figure 19 shows the final anisotropically adapted mesh. We observe strong anisotropic refinement along the layers, again with high polynomial degrees in the elements close to the boundaries.
In the interior of the domain, our algorithm has selected biquadratic approximations on relatively large elements.

In Figure 20 we show magnifications of the central left region \((-1, -0.5) \times (-0.5, 0)\) and the upper-left corner \((-1, -0.75) \times (0.75, 1)\) of the adapted mesh. In the first plot (left), anisotropic mesh refinement is strongly applied near the left boundary \(x_1 = -1\). In the second plot (right), we observe a combination of isotropic and anisotropic elements on the left boundary, while anisotropic refinement is dominating again on the upper boundary \(x_2 = 1\).
Figure 19: Example 4 with $\varepsilon = 10^{-6}$. Final adapted mesh with anisotropic refinement.

Figure 20: Example 4 with $\varepsilon = 10^{-6}$: Zooms into $(-1, -0.5) \times (-0.5, 0)$ (left) and $(-1, -0.75) \times (0.75, 1)$ (right).
6. Conclusions

We have derived an a-posteriori error estimator for DG discretizations of convection-diffusion problems on anisotropically refined meshes. We have proved its reliability, up to an alignment measure which takes into account the possible anisotropy of the underlying meshes. The proof is based on the $hp$-version averaging operator of [7], appropriately scaled to anisotropic elements.

While the introduction of an alignment measure may not be completely satisfactory from a theoretical point of view, our numerical experiments indicate that it becomes of moderate size as soon as boundary layers have been sufficiently resolved, and that in this regime the effectivity indices behave practically uniformly. Our tests further indicate that anisotropic $hp$-adaptive DG algorithms are superior to isotropic ones by orders of magnitude, provided that the layers are properly aligned with the meshes.

Let us also mention a number of possible extensions of our work. An important item is the use of anisotropic polynomial degrees in the adaptive algorithms, which may be desirable to resolve boundary layers most effectively. Since our DG method is based on tensor-product polynomial spaces with respect to master element coordinates, anisotropic polynomial degrees can be incorporated in the numerical scheme with only minor modifications. Regarding the theoretical analysis, one of the key difficulties will be the construction and analysis of a suitable averaging operator in this setting. This will be addressed elsewhere.

Another valuable direction for future research is the extension of our analysis to non-affinely mapped quadrilaterals. For example, this seems possible for the class of anisotropic boundary-layer meshes introduced in [30, Section 3.2], where the elemental mappings $F_K$ are factored into $F_K = \tilde{F}_K \circ G_K$. The mapping $G_K$ is a combination of a dilation and a translation which maps the reference element $\hat{K}$ into an anisotropic rectangle of the form $(0,h_x) \times (0,h_y)$, while $\tilde{F}_K$ is a smooth mapping whose derivatives are uniformly bounded.

Finally, the generalization of our approach to three-dimensional problems is possible by anisotropically scaling the approximation estimates for the three-dimensional $hp$-averaging operator constructed in [6]. This is the subject of ongoing research.
