MAXIMIZING SUPERMODULAR FUNCTIONS ON PRODUCT LATTICES, WITH APPLICATION TO MAXIMUM CONSTRAINT SATISFACTION

ANDREI KROKHIN† AND BENOIT LAROSE‡

Abstract. Recently, a strong link has been discovered between supermodularity on lattices and tractability of optimization problems known as maximum constraint satisfaction problems. This paper strengthens this link. We study the problem of maximizing a supermodular function which is defined on a product of \( n \) copies of a fixed finite lattice and given by an oracle. We exhibit a large class of finite lattices for which this problem can be solved in oracle-polynomial time in \( n \). We also obtain new large classes of tractable maximum constraint satisfaction problems.

Key words. supermodular function, lattices, optimization, tractability, constraint satisfaction

DOI. 10.1137/060669565

1. Introduction. Sub- and supermodular set functions are special real-valued functions defined on the powerset of a set. They are well studied in combinatorics (see bibliographical survey [10]) and have numerous applications in combinatorial optimization [9, 11] and elsewhere (see, e.g., [24, 28]). Minimization of submodular set functions is one of the most well-known tractable problems in combinatorial optimization [11, 27]. Examples of other combinatorial problems that can be solved by using submodular set function minimization include the minimum \( s\)-\( t \) cut problem in networks and finding the largest common independent set in two matroids. The submodular set function minimization problem was also considered for various relaxations of submodular functions such as intersecting or crossing submodular functions. Such relaxations are either defined on some family of subsets of a set, or use a slightly modified form of submodularity [27].

A more general form of sub- and supermodularity is the one where functions are defined on general (i.e., algebraic) lattices [28]. This form of supermodularity is very popular in financial and actuarial mathematics (see, e.g., supermodular games [28] and supermodular order on multivariate distributions [23, 25]), but it is relatively little studied in combinatorics and optimization (see, e.g., section 60.3a of [27]), except for the special case when the lattice is a chain, i.e., a totally ordered set. Sub- and supermodular functions on finite chains can be alternatively represented by matrices and arrays which are called Monge and anti-Monge, respectively, matrices and arrays. Such matrices and arrays are used to identify tractable cases of hard optimization problems such as TSP [1].
Recently, the general form of supermodularity (on lattices) has been applied to classify the complexity of maximum constraint satisfaction problems which are very actively studied optimization problems in artificial intelligence [6] and complexity theory [5]. In a maximum constraint satisfaction problem, informally speaking, one is given a finite collection of constraints on overlapping sets of variables, and the goal is to find an assignment of values to the variables with a maximum number (or total weight) of satisfied constraints. Some recent papers [3, 8, 19] discovered that there is a strong link between supermodularity on lattices and tractability of maximum constraint satisfaction problems with a restricted set of allowed constraints, and developing this connection is the main aim of this paper.

2. Sub- and supermodularity, and lattices. In this section we describe the problem of maximizing a supermodular function on a product lattice.

Definition 2.1. Let \( A \) be finite set. A function \( f : \mathcal{P}(A) \to \mathbb{R} \) is called a supermodular set function (on \( A \)) if the inequality
\[
f(X) + f(Y) \leq f(X \cap Y) + f(X \cup Y)
\]
holds for all \( X, Y \subseteq A \), and it is called submodular if the inverse inequality holds for all \( X, Y \).

The submodular function minimization problem is, given a submodular function \( f \) on \( A \), to find a subset \( X \subseteq A \) with minimum \( f(X) \). It is known [11, 17, 16, 26, 27] that a submodular function on a set \( A \) can be minimized in polynomial time (in \(|A|\)) provided getting a value of \( f \) is a primitive operation.

A partial order on a set \( D \) is called a lattice order if, for every \( x, y \in D \), there exists a greatest lower bound \( x \sqcap y \) and a least upper bound \( x \sqcup y \). The corresponding algebra \( \mathcal{L} = (D, \sqcap, \sqcup) \) is called a lattice. A subset of \( D \) closed under the operations \( \sqcap \) and \( \sqcup \) is called a sublattice of \( \mathcal{L} \). If \( \mathcal{L}_i \) is a lattice on \( D_i \), \( i = 1, \ldots, n \), then the product lattice \( \mathcal{L}_1 \times \cdots \times \mathcal{L}_n \) is a lattice with base set \( D_1 \times \cdots \times D_n \) and operations acting componentwise. The lattice \( \mathcal{L}^n \) is the (direct) product of \( n \) copies of \( \mathcal{L} \), and it is known as the \( n \)-th power of \( \mathcal{L} \). For more information about lattices, see [13].

Definition 2.2. Let \( \mathcal{L} \) be a lattice on \( D \). A function \( f : \mathcal{L}^n \to \mathbb{R} \) is called supermodular on \( \mathcal{L} \) if
\[
f(a) + f(b) \leq f(a \sqcap b) + f(a \sqcup b) \quad \text{for all } a, b \in \mathcal{L}^n,
\]
and \( f \) is called submodular on \( \mathcal{L} \) if the inverse inequality holds.

If \( A \) is a set with \(|A| = n\), then, by identifying subsets of \( A \) with 0-1 \( n \)-tuples, one can easily check that the submodular (set) functions on \( A \) are simply the \( n \)-ary submodular functions on a lattice on \( \{0, 1\} \) with order 0 < 1. Therefore, it is natural to consider the problem of minimizing the submodular functions on a given fixed finite lattice \( \mathcal{L} \), in the following form:

**Instance:** A number \( n \geq 1 \) and a submodular function \( f \) on \( \mathcal{L}^n \).

**Goal:** Find an element \( a \in \mathcal{L}^n \) such that \( f(a) = \min \{ f(b) | b \in \mathcal{L}^n \} \).

We will denote this problem by SFM(\( \mathcal{L} \)). We will say that SFM(\( \mathcal{L} \)) is oracle-tractable if it can be solved in polynomial time in \( n \) (provided getting the value of \( f \) on a tuple is a primitive operation). It was mentioned in [3] as an open question whether or not SFM(\( \mathcal{L} \)) is oracle-tractable for any fixed lattice \( \mathcal{L} \). This question was motivated in [3] by its applications in constraint satisfaction which we will describe in the next section.
Note that a function $f$ is submodular if and only if $-f$ is supermodular. Therefore, the SFM($L$) problem can also be understood as the supermodular function maximization problem. We will always use this reformulation because we will later apply algorithms for SFM($L$) to solve certain maximization problems.

Recall that a lattice is called distributive if it can be represented by subsets of a set $A$, where the operations $\cap$ and $\cup$ are interpreted as set-theoretic intersection and union, respectively. Note that, in some earlier papers on submodular functions, a family of subsets closed under intersection and union is simply called a lattice family (or a ring family). The following result is proved in section 49.3 of [27] (see also [26]).

**Theorem 2.3.** A submodular function defined on a lattice family $L$ on a set $A$ can be minimized in polynomial time in $|A|$, provided we can compute in polynomial time the largest and the smallest sets in the family, and the preorder $\preceq$ on $A$ defined as follows: $u \preceq v$ if and only if each set $U \in L$ containing $v$ also contains $u$.

Assume that we fix a finite distributive lattice $L$. It is well known that $L$ can be represented by subsets of a set $A$ such that $|A| \leq |L|$. Clearly, we can compute in constant time the sets (as 0-1 $|A|$-tuples) representing the largest and the smallest elements of $L$, and we can also compute the preorder $\preceq$ in constant time. Obviously, for any $n$, the lattice $L^n$ can be represented by subsets of a set $B$ of cardinality $n|A|$ (since an element of $L$ is represented by using $|A|$ bits), while the representations for the largest and the smallest elements of $L^n$ and the preorder for $L^n$ can be trivially obtained from those for $L$. It follows that we can solve the problem SFM($L$) in polynomial time in $n$ (in fact, in $n|L|$, but $|L|$ is a constant).

To the best of our knowledge, there was up to now not a single nondistributive finite lattice $L$ for which the problem SFM($L$) is known to be oracle-tractable. We will provide such examples in this paper.

The problem of minimizing submodular functions on nondistributive lattices was mentioned in [17]. However, it was not clear in that paper what the parameter should be in this case, since, in combinatorics, submodular functions are traditionally considered to be defined on (some or all) subsets of a set, and the standard parameter in such situations was always the cardinality of the set. We believe that our formulation of the problem SFM($L$) is an appropriate form of generalization of the standard SFM problem to the case of arbitrary lattices.

We will generalize this problem even further, by considering classes of finite lattices. Let $C$ be a fixed finite class of finite lattices. Define the optimization problem SFM($C$) as follows:

**Instance:** A lattice $L' = L_1 \times \ldots \times L_n$ such that $L_i \in C$ for all $1 \leq i \leq n$, and a supermodular function $f$ on $L'$.

**Goal:** Find an element $a \in L'$ such that $f(a) = \max \{ f(b) \mid b \in L' \}$.

One can extend the notion of oracle-tractability to the problems SFM($C$) in a natural way, assuming that an instance is given by an $n$-tuple of names of lattices in the product and by an oracle for the function $f$. For any finite class of finite distributive lattices one can follow the same procedure as for a single distributive lattice, so, clearly, the following statement holds.

**Proposition 2.4.** SFM($C$) is oracle-tractable for any finite class $C$ of finite distributive lattices.

### 3. Maximum constraint satisfaction.

Maximum constraint satisfaction problems are well-studied combinatorial optimization problems. The standard example of such problems are MAX $k$-CUT and MAX $k$-SAT.
Let $D$ denote a finite set with $|D| > 1$. Let $R_D^{(m)}$ denote the set of all $m$-ary predicates over $D$, that is, functions from $D^m$ to $\{0,1\}$, and let $R_D = \bigcup_{m=1}^{\infty} R_D^{(m)}$. Also, let $\mathbb{Z}^+$ denote the set of all nonnegative integers.

**Definition 3.1.** A constraint over a set of variables $V = \{x_1, x_2, \ldots, x_n\}$ is an expression of the form $f(x)$, where

- $f \in R_D^{(m)}$ is called the constraint predicate, and
- $x = (x_{i_1}, \ldots, x_{i_m})$ is called the constraint scope.

The constraint $f$ is said to be satisfied on a tuple $a = (a_{i_1}, \ldots, a_{i_m}) \in D^m$ if $f(a) = 1$.

**Definition 3.2.** For a finite $F \subseteq R_D$, an instance of $\text{Max CSP}(F)$ is a pair $(V,C)$, where

- $V = \{x_1, \ldots, x_n\}$ is a set of variables taking their values from the set $D$,
- $C$ is a collection of constraints $f_1(x_1), \ldots, f_q(x_q)$ over $V$, where $f_i \in F$ for all $1 \leq i \leq q$.

The goal is to find an assignment $\varphi : V \rightarrow D$ that maximizes the number of satisfied constraints, that is, to maximize the function $f : D^n \rightarrow \mathbb{Z}^+$, defined by $f(x_1, \ldots, x_n) = \sum_{i=1}^q f_i(x_i)$. If the constraints have (positive integral) weights $\varrho_i$, $1 \leq i \leq q$, then the goal is to maximize the total weight of satisfied constraints, that is, maximize the function $f : D^n \rightarrow \mathbb{Z}^+$, defined by $f(x_1, \ldots, x_n) = \sum_{i=1}^q \varrho_i \cdot f_i(x_i)$.

**Example 3.3 (Max $k$-Cut).** In the Max $k$-Cut problem, one is given an undirected graph $G = (V,E)$ with weighted edges, and the goal is to find a partition of $V$ into $k$ parts, $V = V_0 \cup V_1 \cup \cdots \cup V_{k-1}$, maximizing the total weight of edges with endpoints in different parts. This problem is exactly the $\text{Max CSP}(\{\neq_k\})$ problem where $\neq_k$ is the binary disequality predicate on $\{0,1,\ldots,k-1\}$. To see this, think of vertices of a given graph as variables, and apply the predicate to every pair of variables $x,y$ such that $(x,y)$ is an edge in the graph, while keeping all weights the same.

Since predicates are functions, one can consider supermodular predicates on a lattice. For a finite lattice $L$, we will denote by $\text{Spmod}_L$ the set of all predicates that are supermodular on $L$.

It is easy to see that if $f(x_1, \ldots, x_n) = \sum_{i=1}^q \varrho_i \cdot f_i(x_i)$ and, for some lattice $L$, every $f_i$ is supermodular on $L$, then $f$ is also supermodular on $L$. Moreover, it is clear that one can compute the value of $f$ on a given tuple in linear time in the size of the instance. Hence, we immediately obtain the following lemma.

**Lemma 3.4.** Let $L$ be a finite lattice such that the problem $\text{SFM}(L)$ is oracle-tractable. Then, for any finite set $F \subseteq \text{Spmod}_L$, the problem $\text{Max CSP}(F)$ is tractable.

It is intriguing that all known tractable problems $\text{Max CSP}(F)$ are essentially (i.e., possibly, after removing redundant elements from $D$) of this form (i.e., with $F \subseteq \text{Spmod}_L$ for some lattice $L$ on $D$). In particular, it is known [3] (and follows from Proposition 2.4 and Lemma 3.4) that $\text{Max CSP}(F)$ is tractable whenever $F$ consists of supermodular predicates on some distributive lattice.

In the rest of this section, we present evidence that supermodularity on lattices probably is the right tool for studying the complexity of problems $\text{Max CSP}(F)$.

First, we will consider a form of supermodular constraints that can be defined on any lattice.

**Definition 3.5.** A predicate $f \in R_D^{(m)}$ will be called 2-monotone\(^1\) on a lattice $L$

---

\(^1\)In [3], such predicates are called generalized 2-monotone.
on $D$ if it can be expressed as follows:

\[(3.1) \quad f(x) = 1 \Leftrightarrow ((x_1 \sqsubseteq a_{i_1}) \land \ldots \land (x_i \sqsubseteq a_{i_i})) \lor ((x_j \sqsupseteq b_{j_1}) \land \ldots \land (x_t \sqsupseteq b_{t_i})), \]

where $x = (x_1, \ldots, x_n)$, $a_{i_1}, \ldots, a_{i_i}, b_{j_1}, \ldots, b_{t_i} \in D$, and either of the two disjuncts may be empty (i.e., the value of $s$ or $t$ may be zero).

It is straightforward to check that every 2-monotone predicate on a lattice is supermodular on it. The next theorem is, to the best of our knowledge, the only one available on the complexity of supermodular constraints on arbitrary lattices.

**Theorem 3.6 (see [3]).** Let $L$ be a lattice on a finite set $D$. If $F$ consists of 2-monotone predicates on $L$, then $\text{Max CSP}(F)$ is tractable.

Note that 2-monotone predicates can be defined on any poset, since the definition does not use the property of the order to be lattice. However, it was shown in [20] that if $F$ consists of all binary 2-monotone predicates on a *nonlattice* poset, then $\text{Max CSP}(F)$ is $\text{NP}$-hard.

An endomorphism of $F$ is a unary operation $\pi$ on $D$ such that, for all $f \in F$ and all $(a_1, \ldots, a_n) \in D^n$, we have $f(a_1, \ldots, a_n) = 1 \Rightarrow f(\pi(a_1), \ldots, \pi(a_n)) = 1$. We say that $F$ is a core if every endomorphism of $F$ is injective (i.e. a permutation).

The intuition here is that if $F$ is not a core, then it has a noninjective endomorphism $\pi$, which implies that, for every assignment $\varphi$, there is another assignment $\pi\varphi$ that satisfies all constraints satisfied by $\varphi$ and uses only a restricted set of values, so the problem $\text{Max CSP}(F)$ can be reduced to a similar problem over this smaller set.

**Theorem 3.7 (see [5, 3, 19]).** Let $|D| \leq 3$, and let $F \subseteq R_D$ be a core. If there is a chain $C$ on $D$ such that $F \subseteq \text{Spmod}_C$, then $\text{Max CSP}(F)$ is tractable. Otherwise, $\text{Max CSP}(F)$ is $\text{NP}$-hard.

For an element $d \in D$, define the unary predicate $u_d$ so that $u_d(x) = 1 \Leftrightarrow x = d$. Let $C_D = \{u_d \mid d \in D\}$.

**Theorem 3.8 (see [7, 8]).** Let $D$ be any finite set, and assume that $C_D \subseteq F \subseteq R_D$. If there is a chain $C$ on $D$ such that $F \subseteq \text{Spmod}_C$, then $\text{Max CSP}(F)$ is tractable. Otherwise, $\text{Max CSP}(F)$ is $\text{NP}$-hard.

Note that (assuming that supermodularity is the right tool) chains are the only lattices that could possibly appear in Theorems 3.7 and 3.8 because, as is easy to check, every lattice with at most three elements is a chain and every predicate of the form $u_d$ is supermodular on a lattice if and only if the lattice is a chain (the latter assertion is essentially Lemma 5.1 of [3]).

However, it is known that classes of supermodular predicates on (essentially) different lattices are pairwise incomparable. More precisely, for any lattice $L$, let $L^\partial$ denote the dual lattice of $L$, i.e., the one obtained from $L$ by reversing the order (or by swapping the lattice operations, which is the same). It is obvious from the definition that the classes of supermodular functions on $L$ and on $L^\partial$ coincide. It was shown in [20] that, for any finite lattice $L'$ (on the same set as $L$) such that $L'$ is neither $L$ nor $L^\partial$, there exists a predicate which is 2-monotone (and hence supermodular) on $L$, but not supermodular on $L'$. Hence, essentially, one cannot exclude *any* lattice from these considerations.

It follows that the problem $\text{SPM}(L)$ restricted to supermodular functions on a nondistributive lattice $L$, such as the functions that can appear in instances of $\text{Max CSP}(F)$, is of special interest.

It is a basic fact in lattice theory (see, e.g., [13]) that a lattice is distributive if it does not contain, as a sublattice, one of the two minimal nondistributive lattices: the pentagon $N_5$ and the diamond $M_3$. These two lattices are depicted in Figure 3.1.
It will follow from the results in this paper that \( \text{Max CSP}(F) \) is tractable if \( F \subseteq \text{Spmod}_{\mathcal{N}_5} \) or \( F \subseteq \text{Spmod}_{\mathcal{M}_3} \).

4. SFM and constructions on lattices. In this section we show that tractability of \( \text{SFM}(\mathcal{L}) \) is preserved under certain constructions on lattices, and exhibit a large class of nondistributive lattices for which \( \text{SFM}(\mathcal{L}) \) is tractable.

4.1. General constructions. A congruence on a lattice \( \mathcal{L} \) is an equivalence relation \( \theta \) such that, for all \( a, b, c, d \in \mathcal{L} \), the conditions \( a\theta b \) and \( c\theta d \) imply that both \((a \cap b)\theta (b \cap d)\) and \((a \cup c)\theta (b \cup d)\) hold.

If \( \theta \) is a congruence on \( \mathcal{L} \) and \( a \in \mathcal{L} \), then let \( a[\theta] \) denote the \( \theta \)-class containing \( a \). It is well known that every \( \theta \)-class is a sublattice of \( \mathcal{L} \). It is also well known that the family of all \( \theta \)-classes forms a lattice, called a factor-lattice of \( \mathcal{L} \) and denoted \( \mathcal{L}/\theta \), with operations defined as follows: \( a[\theta] \cap a'[\theta] = (a \cap a')[\theta] \) and \( a[\theta] \cup a'[\theta] = (a \cup a')[\theta] \).

We will now introduce a certain notion of a product of classes of lattices that was intensively studied in lattice theory (see, e.g., [14] or pp. 489–490 of [13]).

**Definition 4.1.** If \( \mathcal{V} \) and \( \mathcal{W} \) are classes of lattices, then their Mal’tsev product, denoted \( \mathcal{V} \circ \mathcal{W} \), consists of all lattices \( \mathcal{L} \) such that there is a congruence \( \theta \) on \( \mathcal{L} \) with the following properties:
1. the lattice \( \mathcal{L}/\theta \) belongs to \( \mathcal{W} \),
2. every \( \theta \)-class is a lattice from \( \mathcal{V} \).

Let \( \mathcal{D} \) denote the class of all distributive lattices, let \( \mathcal{D}_k \) denote the class of all distributive lattices with at most \( k \) elements, and let \( \mathcal{D}_{\text{fin}} \) denote the class of all finite lattices from \( \mathcal{D} \).

**Example 4.2.** The lattice \( \mathcal{N}_5 \) belongs to \( \mathcal{D}_3 \circ \mathcal{D}_2 \). It is easy to check that the equivalence relation \( \theta \) whose two classes are within the ovals in Figure 4.1 is a congruence. The classes of the congruence are distributive lattices (chains), and the lattice \( \mathcal{N}_5/\theta \) is a distributive lattice (a two-element chain).

**Theorem 4.3.** Suppose that \( \mathcal{V}, \mathcal{W} \) are finite classes of finite lattices. If \( \text{SFM}(\mathcal{V}) \) and \( \text{SFM}(\mathcal{W}) \) are both oracle-tractable, then \( \text{SFM}(\mathcal{V} \circ \mathcal{W}) \) is oracle-tractable as well.

**Proof.** Let \( \mathcal{L}' = \mathcal{L}_1 \times \cdots \times \mathcal{L}_n \) such that \( \mathcal{L}_i \in \mathcal{V} \circ \mathcal{W} \) for all \( 1 \leq i \leq n \). Then, for every \( 1 \leq i \leq n \), there exist congruences \( \theta_i \) such that the lattices \( \mathcal{K}_i = \mathcal{L}_i/\theta_i \) belong to \( \mathcal{W} \) and every \( \theta_i \)-class belongs to \( \mathcal{V} \).

Define a function \( f' \) on \( K = K_1 \times \cdots \times K_n \) by letting
\[
f'(a_1[\theta_1], \ldots, a_n[\theta_n]) = \max_{i=1}^n f|_{a_i[\theta_i]}(a_1[\theta_1], \ldots, a_n[\theta_n]).
\]

Let us check that \( f' \) is a supermodular function on \( K \). Take two arbitrary elements in \( K \), say \((a_1[\theta_1], \ldots, a_n[\theta_n])\) and \((b_1[\theta_1], \ldots, b_n[\theta_n])\). Choose \( a_i', b_i', 1 \leq i \leq n \), so that \( a_i\theta_i a_i' \) and \( b_i\theta_i b_i' \) for all \( 1 \leq i \leq n \), and \( f'(a_1[\theta_1], \ldots, a_n[\theta_n]) = f(a_1', \ldots, a_n') \) and
f'(b_1[\theta_1], \ldots, b_n[\theta_n]) = f(b'_1, \ldots, b'_n). Since each \theta_i is a congruence, it follows that
\[
f'(a_1[\theta_1], \ldots, a_n[\theta_n]) + f'(b_1[\theta_1], \ldots, b_n[\theta_n]) = f(a'_1, \ldots, a'_n) + f(b'_1, \ldots, b'_n)
\]
\[
\leq f(a'_1 \land b'_1, \ldots, a'_n \land b'_n) + f(a'_1 \lor b'_1, \ldots, a'_n \lor b'_n)
\]
\[
\leq f'((a'_1 \land b'_1)[\theta_1], \ldots, (a'_n \land b'_n)[\theta_n]) + f'((a'_1 \lor b'_1)[\theta_1], \ldots, (a'_n \lor b'_n)[\theta_n])
\]
\[
= f'((a_1 \land b_1)[\theta_1], \ldots, (a_n \land b_n)[\theta_n]) + f'((a_1 \lor b_1)[\theta_1], \ldots, (a_n \lor b_n)[\theta_n])
\]
\[
= f'(a_1[\theta_1] \land b_1[\theta_1], \ldots, a_n[\theta_n] \land b_n[\theta_n]) + f'(a_1[\theta_1] \lor b_1[\theta_1], \ldots, a_n[\theta_n] \lor b_n[\theta_n]).
\]

Since \mathcal{K} is a direct product of lattices from \mathcal{W}, we infer that \(f'\) can be maximized in polynomial time if the evaluation of \(f'\) on a given tuple is a primitive operation. That is, \(f'\) can be maximized in at most \(p_1(n)\) number of steps, where \(p_1\) is a fixed polynomial, and some of the steps are evaluations of \(f'\) on a given element of \(\mathcal{K}\).

Assume that SFM(\(\mathcal{V}\)) can be solved in \(p_2(n)\) steps, some of which are function evaluations. Now, to prove the theorem, it suffices to show that \(f'\) can be evaluated on any given element of \(\mathcal{K}\) in \(p_2(n)\) steps (assuming that evaluating \(f\) on a given element of \(\mathcal{L}'\) is a primitive operation). Fix an element \((a_1[\theta_1], \ldots, a_n[\theta_n])\) of \(\mathcal{K}\). The goal now is to maximize \(f\) on \(a_1[\theta_1] \times \cdots \times a_n[\theta_n]\). Every \(a_i[\theta_i]\) is a lattice from \(\mathcal{V}\), so evaluating \(f'(a_1[\theta_1], \ldots, a_n[\theta_n])\) can be done in \(p_2(n)\) steps by assumption of the theorem. Hence, \(f\) can be maximized in \(p_1(p_2(n))\) steps, some of which are evaluations of \(f\) on a given tuple.

**Corollary 4.4.** If \(\mathcal{L}_1\) and \(\mathcal{L}_2\) are finite lattices such that SFM(\(\mathcal{L}_i\)) is oracle-tractable for \(i = 1, 2\), then SFM(\(\mathcal{L}_1 \times \mathcal{L}_2\)) is oracle-tractable as well.

**Proof.** Let \(\mathcal{V} = \{\mathcal{L}_1\}\) and \(\mathcal{W} = \{\mathcal{L}_2\}\). It is immediate that SFM(\(\mathcal{V}\)) and SFM(\(\mathcal{W}\)) are oracle-tractable. The lattice \(\mathcal{L}' = \mathcal{L}_1 \times \mathcal{L}_2\) belongs to \(\mathcal{V} \circ \mathcal{W}\). Indeed, the relation \(\theta\) on \(\mathcal{L}'\) defined so that \((a_1, b_1) \theta (a_2, b_2)\) if and only if \(b_1 = b_2\) is a congruence such that \(\mathcal{L}'/\theta\) is isomorphic to \(\mathcal{L}_2\) while every \(\theta\)-class is isomorphic to \(\mathcal{L}_1\). Clearly, when maximizing an \(n\)-ary supermodular function on \(\mathcal{L}_1 \times \mathcal{L}_2\), one can identify \(\mathcal{L}'/\theta\) with \(\mathcal{L}_2\) and every every \(\theta\)-class with \(\mathcal{L}_1\). The result now follows from Theorem 4.3.

**Definition 4.5.** A mapping \(\varphi\) from a lattice \(\mathcal{L}_1\) to a lattice \(\mathcal{L}_2\) is called a homomorphism if, for all \(a, b \in \mathcal{L}_1\), it holds that \(\varphi(a \land b) = \varphi(a) \land \varphi(b)\) and \(\varphi(a \lor b) = \varphi(a) \lor \varphi(b)\). If such a mapping \(\varphi\) is onto, then \(\mathcal{L}_2\) is said to be a homomorphic image of \(\mathcal{L}_1\).
The lattice $\hat{L}$.

**Theorem 4.6.** Fix a finite lattice $\mathcal{L}$. If $\mathcal{L}$ is a homomorphic image of some finite lattice $\mathcal{L}_1$ such that $\text{SFM}(\mathcal{L}_1)$ is oracle-tractable, then $\text{SFM}(\mathcal{L})$ is oracle-tractable as well.

**Proof.** Every supermodular function $f$ on $\mathcal{L}^n$ can be transformed into a supermodular function $f_1$ on $\mathcal{L}_1^n$ by letting $f_1(a_1, \ldots, a_n) = f(\varphi(a_1), \ldots, \varphi(a_n))$ where $\varphi$ is a surjective homomorphism from $\mathcal{L}_1$ to $\mathcal{L}$. It is straightforward to check that $f_1$ is indeed supermodular on $\mathcal{L}_1$. Since $\varphi$ is surjective, the maximum of $f_1$ coincides with the maximum of $f$. By assumption, one can find a tuple $a$ maximizing $f_1$ in polynomial time in $n$, and the tuple maximizing $f$ is obtained from $a$ by applying $\varphi$ componentwise.

It is clear, say, since the pentagon belongs to $D_3 \circ D_2$, that Theorem 4.3 extends (compared to $D_{\text{fin}}$) the class of lattices $\mathcal{L}$ for which $\text{SFM}(\mathcal{L})$ is proved to be oracle-tractable. We note that Theorem 4.6 further extends this class. Consider, for example, the lattice $\hat{L}$ shown in Figure 4.2. It is shown in the proof of Theorem 1 of [14] that this lattice is a homomorphic image of a lattice belonging to $(D_4 \circ D_4) \circ D_4$, so $\text{SFM}(\hat{L})$ is oracle-tractable. It is easy to verify that this lattice is simple, that is, it has no congruences except for the equality relation and the full binary relation. Lemma 1 of [14] states that if a simple lattice belongs to Mal’tsev product of two classes of lattices, then it belongs to one of these classes. Hence, since $\hat{L}$ is simple and nondistributive, it does not belong to any class obtainable from $D_{\text{fin}}$ by using Mal’tsev product.

It follows from Proposition 2.4 and Theorems 4.3 and 4.6 that if a finite lattice $\mathcal{L}$ belongs to a class obtained from finite sets of distributive lattices by (repeatedly) using Mal’tsev product and also taking homomorphic images, then $\text{SFM}(\mathcal{L})$ is oracle-tractable. What is the family $\mathcal{F}$ of finite lattices $\mathcal{L}$ which can be obtained as described above? Unfortunately, it seems quite difficult to give a precise characterization of this family because, by [22], the process of repeatedly applying Mal’tsev product to $\mathcal{D}$ results in different classes of lattices for different orders of applying the operation. However, in the next subsection we describe a well-understood and rich subclass of $\mathcal{F}$, which can be obtained by repeatedly applying Mal’tsev product only to $D_2$. The subclass consists of the so-called bounded finite lattices.

We will now describe some lattices that definitely do not belong to the family $\mathcal{F}$. For $t \geq 3$, a $t$-diamond (or simply a diamond), denoted $\mathcal{M}_t$, is a lattice on an $(t+2)$-element set such that $0, 1, 1_{\mathcal{M}_t}$ are the least and the greatest element, respectively, and all $t$ elements in $\mathcal{M}_t \setminus \{0_{\mathcal{M}_t}, 1_{\mathcal{M}_t}\}$ are pairwise incomparable. The Hasse diagram of $\mathcal{M}_t$ is given in Figure 4.3. Note that $\mathcal{M}_3$ is often referred to as the diamond. It is well known and easy to check that every diamond is a simple nondistributive lattice. In addition, every diamond has the property that, for every finite lattice $\mathcal{L}$ having
\( \mathcal{M}_t \) as a homomorphic image, \( \mathcal{L} \) also contains \( \mathcal{M}_t \) as a sublattice (see Lemma 6.21 of [15] or the more general Theorem 2.47 of [18]). Hence, in order to show that no diamond belongs to \( \mathcal{F} \), it is sufficient to prove that if a finite lattice \( \mathcal{L} \) containing \( \mathcal{M}_t \) as a sublattice belongs to \( \mathcal{X} \circ \mathcal{Y} \), then at least one of these two classes contains a lattice with the same property. So assume that \( \mathcal{L} \in \mathcal{X} \circ \mathcal{Y} \). By definition, \( \mathcal{L} \) has a congruence \( \theta \) such that \( \mathcal{L}/\theta \in \mathcal{Y} \) and every \( \theta \)-class is in \( \mathcal{X} \). It is well known and easy to show that the restriction \( \theta' \) of \( \theta \) on \( \mathcal{M}_t \) is a congruence of \( \mathcal{M}_t \). By simplicity of \( \mathcal{M}_t \), all the elements of \( \mathcal{M}_t \) belong either to a single \( \theta' \)-class or to pairwise different \( \theta' \)-classes. In the former case, \( \mathcal{M}_t \) is entirely contained in some \( \theta \)-class, so this class is the required lattice in \( \mathcal{X} \). In the latter case, \( \mathcal{L}/\theta \in \mathcal{Y} \) is the required lattice. This argument can be easily generalized to show that, in fact, no lattice containing \( \mathcal{M}_3 \) as a sublattice belongs to \( \mathcal{F} \).

Even though we have been unable to prove that \( \text{SFM}(\mathcal{M}_t) \) is oracle-tractable, we will show in section 5 that the problems \( \text{Max CSP}(\mathcal{F}) \) with \( \mathcal{F} \subseteq \text{Spmod}_{\mathcal{M}_t} \) are tractable.

4.2. Finite bounded lattices. Let \( \mathcal{L} \) be a lattice and \( u \sqsubseteq v \) two comparable (and not necessarily distinct) elements of \( \mathcal{L} \). Let \( I \) denote the interval \( [u, v] = \{ x \in \mathcal{L} | u \sqsubseteq x \sqsubseteq v \} \) in \( \mathcal{L} \).

DEFINITION 4.7. The lattice \( \mathcal{L}[I] \) is said to be obtained from \( \mathcal{L} \) by doubling the interval \( I \) if the base set of \( \mathcal{L}[I] \) is \( (\mathcal{L} \setminus I) \cup (I \times \{0, 1\}) \) and \( x \sqsubseteq y \) holds in \( \mathcal{L}[I] \) if and only if

- \( x \sqsubseteq y \) in \( \mathcal{L} \) and \( x, y \not\in I \), or
- \( x \in \mathcal{L} \setminus I, y = (b, j) \) and \( x \sqsubseteq b \) in \( \mathcal{L} \), or
- \( x = (a, i), y \in \mathcal{L} \setminus I \) and \( a \sqsubseteq y \) in \( \mathcal{L} \), or
- \( x = (a, i), y = (b, j) \) such that \( a, b \in I \) and \( a \sqsubseteq b \) in \( \mathcal{L} \), and \( i \leq j \).

Essentially, doubling an interval \( I \) in \( \mathcal{L} \) means replacing it with \( I \times \{0, 1\} \).

DEFINITION 4.8. A finite lattice \( \mathcal{L} \) is called bounded if there is a sequence \( \mathcal{L}_1, \ldots , \mathcal{L}_n \) such that \( \mathcal{L}_1 \) is one-element, \( \mathcal{L}_n \) is isomorphic to \( \mathcal{L} \), and, for \( j = 1, \ldots , n-1 \), there exists an interval \( I_j \) in \( \mathcal{L}_j \) such that \( \mathcal{L}_{j+1} \) is isomorphic to \( \mathcal{L}_j[I_j] \).

In other words, a finite lattice is called bounded if it can be obtained from the one-element lattice by successive doubling of intervals. For example, Figure 4.4 demonstrates that the pentagon is a bounded lattice, while it is not hard to check the lattice \( \mathcal{L} \) from Figure 4.2 is not bounded. Bounded lattices play an important role in lattice theory [18]. The name “bounded” comes from an equivalent characterization of such lattices, which is usually used as the definition (but does not play any role in this

\footnote{\text{Not to be confused with posets that have both the least and the greatest element.}}
Obtaining the pentagon by doubling intervals (in three steps). In each step, the white elements indicate the interval to be doubled.

Paper). Theorem 2.46 of [18] states that a finite lattice \( \mathcal{L} \) is bounded if and only if there exists a free lattice \( \mathcal{FL} \) and a congruence \( \alpha \) on \( \mathcal{FL} \) such that \( \mathcal{L} \) is isomorphic to \( \mathcal{FL}/\alpha \), and every \( \alpha \)-class in \( \mathcal{FL} \) has both the least and the greatest element.

It is easy to check that for any lattice \( \mathcal{L} \) and any interval \( I \) in \( \mathcal{L} \), the binary relation \( \theta \) on \( \mathcal{L}/I \) defined by the rule

\[
(x, y) \in \theta \iff \text{either } x = y \notin I \text{ or } x = (a, i), y = (a, j) \text{ for some } a \in I
\]

is a congruence of \( \mathcal{L}/I \). Moreover, the lattice \( \mathcal{L}/I/\theta \) is isomorphic to \( \mathcal{L} \), and every \( \theta \)-class is either a one-element lattice \( C_1 \) or a two-element chain \( C_2 \). Therefore, we have that \( \mathcal{L}/I \) belongs to the Mal'tsev product \( \{C_1, C_2\} \circ \{\mathcal{L}\} \). So, if we inductively define \( D_1^2 = D_2 \) and \( D_2^2 = D_2 \circ D_2^{n-1} \) for \( n > 1 \), then we have that every finite bounded lattice belongs to \( D_2^2 \) for a suitable \( n \). Hence, Theorem 4.3 (together with Lemma 3.4) implies the following statement.

**Proposition 4.9.** Let \( \mathcal{L} \) be a fixed finite bounded lattice. Then \( \text{SFM}(\mathcal{L}) \) is oracle-tractable and, for any finite set \( \mathcal{F} \subseteq \text{Spmod}_\mathcal{L} \), \( \text{Max CSP}(\mathcal{F}) \) is tractable.

It is known (see Lemma 2.40 of [18]) that the class of finite bounded lattices is a pseudovariety, that is, it is closed under taking homomorphic images, sublattices, and finite direct products. Since the two-element chain is a bounded lattice, it follows that every finite distributive lattice is bounded. Interestingly, if one allows not only finite, but arbitrary direct products (i.e., direct products of infinitely many lattices), then one can generate all lattices from finite bounded lattices (this fact immediately follows from Theorems 2.25 and 2.44 of [18]). In other words, every (not necessarily finite) lattice is a homomorphic image of a subalgebra of a direct product of (possibly infinitely many) finite bounded lattices. Unfortunately, this fact seems to be useless for the algorithmic aspects which we are interested in.

**5. Max CSP on diamonds.** In this section, we consider problems \( \text{Max CSP}(\mathcal{F}) \) where \( \mathcal{F} \) consists of supermodular predicates on a diamond \( \mathcal{M}_t \) (see Figure 4.3). The middle elements of \( \mathcal{M}_t \) are called atoms. Note that, for each pair of distinct atoms \( a \) and \( b \), we have \( a \cap b = 0_{\mathcal{M}_t} \) and \( a \cup b = 1_{\mathcal{M}_t} \). For simplicity, let \( \mathcal{L} \) denote an arbitrary (fixed) \( t \)-diamond, \( t \geq 3 \), throughout this section.

**5.1. The structure of supermodular predicates on diamonds.** In this subsection, we describe the structure of supermodular predicates on \( \mathcal{L} \) by representing them as logical formulas involving constants (elements of \( \mathcal{L} \)) and the order relation \( \subseteq \) of \( \mathcal{L} \).

For a subset \( D' \subseteq D \), let \( u_{D'} \) denote the predicate such that \( u_{D'}(x) = 1 \iff x \in D' \). The following lemma can be easily derived directly from the definition of supermodularity.

Copyright © by SIAM. Unauthorized reproduction of this article is prohibited.
Lemma 5.1. A unary predicate \( u_{D'} \) is in \( \text{Spmod}_L \) if and only if either both 
0 \( \in \mathcal{L} \), \( 1 \in \mathcal{L} \in D' \) or else \( |D'| \leq 2 \) and at least one of \( 0 \in \mathcal{L}, 1 \in \mathcal{L} \) is in \( D' \).

For a sequence \( y = (x_{i_1}, \ldots, x_{i_m}) \) of variables and a sequence \( c = (c_1, \ldots, c_m) \) of elements of \( \mathcal{L} \), we write \( y \sqsubseteq c \) to denote \( \wedge_{1 \leq s \leq m} (x_{i_s} \sqsubseteq c_{i_s}) \), and the condition \( y \sqsupseteq c \) is defined dually.

**Theorem 5.2.** Every predicate \( f(x_1, \ldots, x_n) \) in \( \text{Spmod}_L \), such that \( f \) takes both values 0 and 1, can be represented as one of the following logical implications:

1. \( \left[ (x_i \sqsubseteq a_1) \lor \cdots \lor (x_i \sqsubseteq a_l) \right] \implies (x_i \sqsubseteq 0) \), where the \( a_j \)'s are atoms;
2. \( \neg(y \sqsubseteq c) \implies (z \sqsubseteq d) \), where \( y \) and \( z \) are some subsequences of \( (x_1, \ldots, x_n) \), and \( c, d \) are tuples of elements of \( \mathcal{L} \) (of corresponding length) such that \( c \) contains no 0 and \( d \) no 1;
3. \( \left[ (x_i \sqsubseteq b_1) \lor \cdots \lor (x_i \sqsubseteq b_k) \lor \neg(y \sqsubseteq c) \right] \implies (x_i \sqsubseteq a) \), where the \( b_j \)'s are atoms, \( y \) does not contain \( x_i \), and \( a \neq 1 \);
4. \( \neg(x_i \sqsubseteq b) \implies \neg(x_i \sqsubseteq a_1) \land \cdots \land \neg(x_i \sqsubseteq a_l) \land (y \sqsubseteq c) \), where the \( a_j \)'s are atoms, \( y \) does not contain \( x_i \), and \( b \neq 0 \);
5. \( \neg(y \sqsubseteq c) \implies \text{false} \), where \( y \) is a subsequence of \( (x_1, \ldots, x_n) \) and \( c \) contains no 1;
6. \( \text{true} \implies (y \sqsubseteq c) \), where \( y \) is a subsequence of \( (x_1, \ldots, x_n) \) and \( c \) contains no 1.

Conversely, every predicate that can be represented in one of the above forms belongs to \( \text{Spmod}_L \).

**Example 5.3.** The unary predicate of type (1) above is the same as \( u_{D'} \) where \( D' = D \setminus \{a_1, \ldots, a_l\} \). The predicates \( u_{D'} \in \text{Spmod}_L \) with \( |D'| \leq 2 \) are the unary predicates of types (5) and (6).

**Remark 5.4.** Note that constraints of types (2), (5), and (6) are 2-monotone on \( L \), while constraints of types (3) and (4) (and most of those of type (1)) are not.

**Proof of Theorem 5.2.** It is straightforward to verify that all of the predicates in the list are actually supermodular. Now we prove the converse. Consider first the case where the predicate \( f \) is essentially unary, i.e., there is a variable \( x_i \) such that \( f(x_1, \ldots, x_n) = u_{D'}(x_i) \) for some \( D' \subset D \). If \( D' = \{x : x \subseteq a\} \) or \( D' = \{x : x \sqsupseteq a\} \) for some atom \( a \), then \( f \) is of the form (5) or (6); otherwise, both \( 0 \in \mathcal{L} \) and \( 1 \in \mathcal{L} \) are in \( D' \) by Lemma 5.1, and if \( a_1, \ldots, a_l \) denote the atoms of the lattice that are not in \( D' \), then it is clear that \( f \) is described by the implication (1).

Now we may assume that \( f \) is not essentially unary. If it is 2-monotone, then it is easy to see that \( f \) must be described by an implication of type (2), (5), or (6). So now we assume that \( f \) is not essentially unary and it is not 2-monotone; we prove that it is described by an implication of type (3) or (4). We require a few claims:

**Claim 0.** The set \( X \) of all tuples \( u \) such that \( f(u) = 1 \) is a sublattice of \( \mathcal{L}^n \), i.e., is closed under join and meet.

This follows immediately from the supermodularity of \( f \).

**Claim 1.** There exist indices \( 1 \leq i_1, \ldots, i_k, j_1, \ldots, j_l \leq n \), atoms \( c_1, \ldots, c_k \) and \( b_1, \ldots, b_l \) of \( \mathcal{L} \) such that \( f(x) = 1 \) if and only if

\[ \neg(x_{i_1} \sqsubseteq c_1) \land \cdots \land \neg(x_{i_k} \sqsubseteq c_k) \lor \neg(x_{j_1} \sqsubseteq b_1) \land \cdots \land \neg(x_{j_l} \sqsubseteq b_l) \].

Notice first that the set \( Z \) of tuples \( u \) such that \( f(u) = 0 \) is convex in \( \mathcal{L}^n \); i.e., if \( u \sqsubseteq v \sqsubseteq w \) with \( f(u) = f(w) = 0 \), then \( f(v) = 0 \). To show this we construct a tuple \( v' \) as follows: for each coordinate \( i \) it is easy to find an element \( v'_i \) such that \( v_i \lor v'_i = u_i \) and \( v_i \land v'_i = v_i \). Hence \( v' \lor v' = u \) and \( v' \sqsubset v' = w \) so by supermodularity of \( f \) neither \( v \) nor \( v' \) is in \( X \). It follows in particular that neither \( 0 \in \mathcal{L} \) nor \( 1 \in \mathcal{L} \) is in
is in element of contain 1

\[ L \in I \]

if \( F \) contain 2 distinct atoms. We consider the first case, and we show that the predicate \( F \) is of type (4). The case where some \( F \) contains 2 atoms is dual and will yield type (3).

Claim 2. Suppose that \( I_i \) contains distinct atoms \( c \) and \( d \) for some \( i \in \{i_1, \ldots, i_k\} \). Then (a) \( i \) is the only index with this property, (b) \( \{j_1, \ldots, j_l\} = \{i\} \), and (c) \( F_i \) does not contain 2 distinct atoms.

We prove (b) first. We have that

\[ f(0, \ldots, 0, c, 0, \ldots, 0) = f(0, \ldots, 0, d, 0, \ldots, 0) = 1 \]

(where \( c \) and \( d \) appear in the \( i \)th position) and by supermodularity it follows that we also have \( f(0, \ldots, 0, 0, 0, \ldots, 0) = 1 \). Since \( I_i \) does not contain \( 1 \), we have that \( x_j \in F_j \) for each \( j \in \{j_1, \ldots, j_l\} \); since \( F_j \) never contains \( 0 \), (b) follows immediately. Since \( \{j_1, \ldots, j_l\} \) is nonempty, (a) follows immediately from (b). Finally, if \( F_i \) contained distinct atoms, then by dualizing the preceding argument we would obtain that \( \{i_1, \ldots, i_k\} = \{i\} \) from which it would follow that \( f \) would be essentially unary, contrary to our assumption. This concludes the proof of the claim.

Let \( b \) denote the minimal element in \( F_i \), and for each index \( s \in \{i_1, \ldots, i_k\} \) different from \( i \) let \( c_s \) denote the (unique) maximal element of \( I_s \); then we can describe \( f \) as follows: \( f(x) = 1 \) if and only if

\[ [x_i \in I_i \land (y \subseteq e)] \lor (x_i \not\subseteq b), \]

where \( y \) is a tuple of variables different from \( x_i \) and \( e \) is the tuple whose entries are the \( c_s \) defined previously. It remains to rewrite the condition \( x_i \in I_i \). Suppose first
that there exists at least one atom of $\mathcal{L}$ outside $I_i$, and let $a_1, \ldots, a_l$ denote the atoms outside $I_i$. Then it is clear that $x_i \in I_i$ if and only if $\neg(x_i \sqsupset a_1) \land \cdots \land \neg(x_i \sqsupset a_l)$ holds, so the predicate $f$ is of type (4) (simply restate the disjunction as an implication).

Now for the last possibility, where $I_i$ contains all of $D$ except $1_\mathcal{L}$; then it is easy to see that $f$ can be described by the following:

$$\neg(x_i \sqsupset b) \land (y \sqsubseteq c) \lor (x_i \sqsupset b),$$

and this completes the proof of the theorem. \qed

5.2. Supermodular constraints on diamonds are tractable.

Theorem 5.5. If $\mathcal{F} \subseteq \text{Spmod}_\mathcal{L}$, then MAX CSP($\mathcal{F}$) can be solved (to optimality) in $O(n^5 \cdot |\mathcal{L}|^3 + q^3)$ time where $n$ is the number of variables and $q$ is the number of constraints in an instance.

Proof. We will show how the problem can be reduced to the well-known tractable problem MIN CUT.

Let $\mathcal{I} = \{\rho_1 : f_1(x_1), \ldots, \rho_q : f_q(x_q)\}$, $q \geq 1$, be an instance of weighted MAX CSP ($\mathcal{F}$), over a set of variables $V = \{x_1, \ldots, x_n\}$.

Construction.

Let $\infty$ denote an integer greater than $\sum \rho_i$. For each constraint $f_i$, fix a representation as described in Theorem 5.2. In the following construction, we will refer to the type of $f_i$ which will be a number from 1 to 6 according to the type of representation.

Every condition of the form $(y \sqsubseteq c)$ will be read as $\bigwedge (x_i \sqsubseteq c_i)$, and every condition of the form $\neg(y \sqsubseteq c)$ as $\bigvee \neg(x_i \sqsubseteq c_i)$, where $i_a$ runs through the indices of variables in $y$. Moreover, we replace every (sub)formula of the form $\neg(x \sqsubseteq 1_\mathcal{L})$ by $\bigvee_{i=1}^{n} \neg(x \sqsubseteq a_i)$, where $a_1, \ldots, a_n$ are the atoms of $\mathcal{L}$.

Next, we construct a digraph $G_T$.

- The vertices of $G_T$ are as follows:
  - $(T, F) \cup \{x_d \mid x \in V,d \in \mathcal{L}\} \cup \{\bar{x}_d \mid x \in V,d \in \mathcal{L} \text{ is an atom}\} \cup \{e_i, \bar{e}_i \mid i = 1, 2, \ldots, q\}$.

  For each $f_i$ of type (5), we identify the vertex $e_i$ with $F$. Similarly, for each $f_i$ of type (6), we identify the vertex $\bar{e}_i$ with $T$.

- The arcs of $G_T$ are defined as follows:
  - For each atom $c$ in $\mathcal{L}$ and for each $x \in V$, there is an arc from $x_0c$ to $xc$ with weight $\infty$, and an arc from $\bar{x}_c$ to $x_1c$ with weight $\infty$.
  - For each pair of distinct atoms $c, d$ in $\mathcal{L}$ and for each $x \in V$, there is an arc from $xc$ to $\bar{x}_d$ with weight $\infty$.
  - For each $f_i$, there is an arc from $\bar{e}_i$ to $e_i$ with weight $\rho_i$.
  - For each $f_i$ of types (1–4), and each subformula of the form $(x \sqsubseteq a)$ or $\neg(x \sqsubseteq a)$ in the consequent of $f_i$, there is an arc from $e_i$ to $x_a$ or $\bar{x}_a$, respectively, with weight $\infty$.
  - For each $f_i$ of types (1–4), and each subformula of the form $(x \sqsubseteq a)$ or $\neg(x \sqsubseteq a)$ in the antecedent of $f_i$, there is an arc from $x_a$ or $\bar{x}_a$, respectively, to $\bar{e}_i$, with weight $\infty$.
  - For each $f_i$ of type (5), and each subformula of the form $\neg(x \sqsubseteq a)$ in it, there is an arc from $\bar{x}_a$ to $\bar{e}_i$ with weight $\infty$.

\footnote{The vertices $x_d$ will correspond to the expressions $x \sqsubseteq d$ and $\bar{x}_d$ to $\neg(x \sqsubseteq d)$.}
For each $f_i$ of type (6), and each subformula of the form $(x \sqsubseteq a)$ in it, there is an arc from $e_i$ to $x_a$ with weight $\infty$.

Arcs with weight less than $\infty$ will be called constraint arcs.

It is easy to see that $G_T$ is a digraph with source $T$ (corresponding to true) and sink $F$ (corresponding to false). Note that paths of nonconstraint arcs between vertices corresponding to any given variable $x \in V$ precisely correspond to logical implications that hold between the corresponding assertions. Throughout the proof, we say “a cut in $G_T$” meaning a $(T, F)$-cut.

Define the deficiency of an assignment $\varphi$ as the difference between $\sum_{i=1}^{q} \rho_i$ and the evaluation of $\varphi$ on $I$. In other words, the deficiency of $\varphi$ is the total weight of constraints not satisfied by $\varphi$. We will prove that minimal cuts in $G_T$ exactly correspond to optimal assignments to $I$. More precisely, we will show that, for each minimal cut in $G_T$ with weight $\rho$, there is an assignment for $I$ with deficiency at most $\rho$, and, for each assignment to $I$ with deficiency $\rho'$, there is a cut in $G_T$ with weight $\rho'$.

The semantics of the construction of $G_T$ will be as follows: the vertices of the form $x_a$ or $\bar{x}_a$ correspond to assertions of the form $x \sqsubseteq a$ or $\neg(x \sqsubseteq a)$, respectively, and arcs denote implications about these assertions. Given a minimal cut in $G_T$, we will call a vertex $x_a$ reaching if $F$ can be reached from it without crossing the cut. Furthermore, if a vertex $x_a$ is reaching, then this will designate that the corresponding assertion is false, and otherwise the corresponding assertion is true. A constraint is not satisfied if and only if the corresponding constraint arc crosses the cut.

Let $C$ be a minimal cut in $G_T$. Obviously, $C$ contains only constraint arcs. First we show that, for every variable $x \in V$, there is a unique minimal element $a \in L$ such that $x_a$ is nonreaching. All we need to show is the following: if $c, d$ are distinct atoms such that both $x_c$ and $x_d$ are both nonreaching, then so is $x_{0_c}$. Assume that, on the contrary, $x_{0_c}$ is reaching. Then there is a path from $x_{0_c}$ to $F$ not crossing the cut. It is easy to notice that such a path has to go through a vertex $\bar{x}_a$ for some atom $a \in L$, since the second vertex on this path must be of the form $x_b$ for some atom $b$, and it is followed either by a vertex $\bar{x}_a$ or else by three vertices $\bar{e}_i, e_i, x_{b'}$ for some $1 \leq i \leq q$ and some atom $b'$. However, we have an arc from at least one of the vertices $x_c, x_d$ to $x_a$, and hence at least one of these vertices would have a path to $F$ not crossing the cut, a contradiction.

Note that, for every $x \in V$, there are no arcs coming out of $x_{1_c}$. Hence, for every $x \in V$, there is a unique minimal element $v \in L$ such that $F$ cannot be reached from $x_v$ without crossing the cut.

Define an assignment $\varphi_C$ as follows:

$$\varphi_C(x)$$

is the unique minimal element $a$ such that $x_a$ is nonreaching.

We now make some observations. Note that, for all $x \in V$ and $a \in L$, we have that $\varphi_C(x) \not\sqsubseteq a$ if and only $x_a$ is nonreaching. Moreover, if $\bar{x}_a$ is reaching, then, for each atom $b \neq a$, we have an arc from $x_b$ to $\bar{x}_a$ meaning that $\varphi_C(x) \not\sqsubseteq b$, and hence $\varphi_C(x) \sqsupseteq a$. Furthermore, if $\bar{x}_a$ is nonreaching, then $\varphi_C(x) \neq a$. Indeed, if $\varphi_C(x) = a$, then $x_b$ is reaching for all atoms $b \neq a$, and, since every path from $x_b$ to $F$ has to go through a vertex $\bar{x}_c$ for some $c$, we have that $\bar{x}_c$ is reaching. Then $c \neq a$, and there is an arc from $x_a$ to $\bar{x}_c$, so $x_a$ is reaching, a contradiction. To summarize, we have the following:

- If a node of the form $x_a$ or $\bar{x}_a$ is reaching, then the corresponding assertion is falsified by the assignment $\varphi_C$.
- If a node of the form $x_a$ is nonreaching, then $\varphi_C(x) \sqsubseteq a$.

• If a node of the form $\bar{x}_a$ is nonreaching, then the truth value of the corresponding assertion is undecided.

Suppose that a constraint arc corresponding to a constraint $f_i$ is not in the cut. We claim that $f_i$ is satisfied by the assignment $\varphi_C$. To show this, we will go through the possible types of $f_i$.

If $f_i$ is of type (1), (2), (5), or (6), then the claim is straightforward. For example, let $f_i$ be of type (1). If the node $x_0$, corresponding to the consequent is reaching, then so are all nodes corresponding to the antecedent. Hence, all atomic formulas are falsified by the assignment $\varphi_C$, and the implication is true. If $x_0$ is nonreaching, then $\varphi_C(x) = 0$, and the constraint is clearly satisfied. The argument for types (2), (5), and (6) is very similar.

Let $f_i$ be of type (3). Then, if the node corresponding to the consequent is nonreaching, then the consequent is satisfied by $\varphi_C$, and so the constraint is satisfied. If this node is reaching, then every node corresponding to the disjuncts in the antecedent is reaching. Then both antecedent and consequent are falsified by $\varphi_C$, and the constraint is satisfied.

Let $f_i$ be of type (4), that is, of the form

$$\neg (x_i \sqsupset b) \implies \neg (x_i \sqsupset a_1) \land \cdots \land \neg (x_i \sqsupset a_l) \land (y \sqsubseteq c).$$

If a node corresponding to some conjunct in the consequent is reaching, then the node corresponding to the antecedent is also reaching. So $\varphi_C(x_i) \sqsupset b$, and the constraint is satisfied. More generally, if the node corresponding to the antecedent is reaching, then the constraint is satisfied regardless of what happens with the consequent. Assume that all nodes corresponding to conjuncts in the consequent and in the antecedent are nonreaching. Then the conjunct $(y \sqsubseteq c)$ is satisfied by $\varphi_C$. Furthermore, we know (see the observations above) that $\varphi_C(x_i) \neq b$, and also that $\varphi_C(x_i) \neq a_s$ for $1 \leq s \leq l$. If $\varphi_C(x_i) = 1$, then both the antecedent and the consequent of $f_i$ are false, and hence $f_i$ is satisfied. Otherwise, $\varphi_C(x_i) \not\sqsubseteq b$ and $\varphi_C(x_i) \not\sqsupset a_s$ for $1 \leq s \leq l$, so $f_i$ is satisfied anyway.

Conversely, let $\varphi$ be an assignment to $\mathcal{I}$, and let $K$ be the set of constraints in $\mathcal{I}$ that are not satisfied by $\varphi$. Consider any path from $T$ to $F$. It is clear that if all constraints corresponding to constraint arcs on this path are satisfied, then we have a chain of valid implications starting from true and finishing at false. Since this is impossible, at least one constraint corresponding to such an arc is not satisfied by $\varphi$. Hence, the constraint arcs corresponding to constraints in $K$ form a cut in $G_T$. Furthermore, by the choice of $K$, the weight of this cut is equal to the deficiency of $\varphi$.

It follows that the standard algorithm [12] for the Min Cut problem can be used to find an optimal assignment for any instance of Max CSP($\mathcal{F}$). This algorithm runs in $O(k^3)$, where $k$ is the number of vertices in the graph. Since the number of vertices in $G_T$ is at most $2(1 + n \cdot |D| + q)$, the result follows.

We remark that a partial converse to Theorem 5.5 was proved in [20] where it is shown that if $\mathcal{F}$ contains all 2-monotone predicates on a diamond and any predicate which is not supermodular on that diamond, then Max CSP($\mathcal{F}$) is NP-hard.

6. Conclusion. We have described a large class of lattices on which the SFM problem is oracle-tractable, and an even larger class of lattices $\mathcal{L}$ such that Max CSP($\mathcal{F}$) is tractable whenever all predicates in $\mathcal{F}$ are supermodular on $\mathcal{L}$. We believe that more progress in the study of maximum constraint satisfaction can be achieved by further blending supermodular optimization and algebraic lattice theory.
The three most standard constructions on algebras (and on lattices in particular) are the forming of homomorphic images, subalgebras, and direct products. We showed (Corollary 4.4 and Theorem 4.6) that two of them preserve oracle-tractability of the problems SFM($\mathcal{L}$). However, it is an open problem whether, for any finite lattice $\mathcal{L}_1$, oracle-tractability of SFM($\mathcal{L}_1$) implies oracle-tractability of SFM($\mathcal{L}_2$) for any sublattice $\mathcal{L}_2$ of $\mathcal{L}_1$.

This paper explores two ways of obtaining tractability results for Max CSP problems—one is via oracle-tractability of the SFM problem, and the other via explicit description of supermodular predicates. One other way that remains to be explored has to do with implicit methods (see [2, 4]) of showing that some predicates can be simulated (or “strictly implemented” [8, 19]) by other predicates. One interesting question in this connection is whether any supermodular predicate on a lattice can be simulated, i.e., strictly implemented, by 2-monotone predicates on that lattice. A positive answer to this question would, together with Theorem 3.6, imply that Max CSP($\mathcal{F}$) is tractable for arbitrary sets $\mathcal{F}$ of supermodular predicates on a lattice.

Finally, we hope that the study of sub- and supermodular functions on lattices will find more applications in combinatorial optimization.
