Vertex Splitting and the Recognition of Trapezoid Graphs

George B. Mertzios∗ Derek G. Corneil†‡

Abstract

Trapezoid graphs are the intersection family of trapezoids where every trapezoid has a pair of opposite sides lying on two parallel lines. These graphs have received considerable attention and lie strictly between permutation graphs (where the trapezoids are lines) and cocomparability graphs (the complement has a transitive orientation). The operation of “vertex splitting”, introduced in [3], first augments a given graph $G$ and then transforms the augmented graph by replacing each of the original graph’s vertices by a pair of new vertices. This “splitted graph” is a permutation graph with special properties if and only if $G$ is a trapezoid graph. Recently vertex splitting has been used to show that the recognition problems for both tolerance and bounded tolerance graphs is NP-complete [11]. Unfortunately, the vertex splitting trapezoid graph recognition algorithm presented in [3] is not correct. In this paper, we present a new way of augmenting the given graph and using vertex splitting such that the resulting algorithm is simpler and faster than the one reported in [3].

Keywords: Trapezoid graphs, permutation graphs, recognition, vertex splitting, polynomial algorithm.

1 Introduction

Consider two parallel horizontal lines, $L_1$, the upper line and $L_2$, the lower line. Various intersection graphs can be defined on objects formed with respect to these two lines. In particular, for permutation graphs, the objects are line segments that have one endpoint on $L_1$ and the other on $L_2$. Generalizing to objects that are trapezoids with one interval on $L_1$ and the opposite interval on $L_2$, we define the trapezoid graphs. Between these two classes of graphs lie the PI (for Point-Interval) graphs where the objects are triangles with one point of the triangle on $L_1$ and the other two points of the triangle on $L_2$ and PI∗ graphs where again the objects are triangles, but now there is no restriction on which line contains one point of the triangle and which line contains two [5]. In particular, permutation graphs are strictly contained in PI graphs, which are strictly contained in PI∗ graphs, which are strictly contained in trapezoid graphs; examples illustrating the strict containments are presented in [2]. Note that a similar definition holds for parallelogram graphs.

The fastest algorithm for determining whether a given graph $G$ is a trapezoid graph, and finding an intersection representation if $G$ is trapezoid, uses a transitive orientation algorithm and requires $O(n^2)$ time [8]; see [12] for an overview. This algorithm appeared in 1994 and uses the fact that $G$ is a trapezoid graph if and only if the complement of $G$ has interval dimension 2, and “takes a transitive orientation algorithm for the complement of $G$ and turns the trapezoid

that the line $T$ lies completely to the left of the line $uv$. Intuitively, if $G$ is a trapezoid graph with a representation $R$, this splitting can be considered as a replacement of the trapezoid $T_v$ representing $v$ in $R$ by two trivial trapezoids, namely, lines, that represent $v_1$ and $v_2$. Then the given graph $G$ is a trapezoid graph if and only if the graph $G'$ produced by vertex splitting is a permutation graph with a specific property.

Although the algorithm reported in [3] is not correct, the concept of vertex splitting has been successfully used in [11] where it is shown that the recognition of tolerance and bounded tolerance graphs is NP-complete, thereby settling a long standing open question. Their proof uses the fact that a graph is a bounded tolerance graph if and only if it is a parallelogram graph [1, 7].

In the present paper, although we also use a vertex splitting approach as in [3], we do so in a very different context. In particular, both before and after splitting we augment the current graph by adding some new vertices and edges. By doing so, we establish structural properties that are needed in the trapezoid recognition algorithm. Our algorithm develops a new way of employing the linear time transitive orientation algorithm of McConnell and Spinrad [9] to show that the graph constructed by these augmentations and splitting is a permutation graph with specific properties. Our trapezoid recognition algorithm is simpler than the one reported in [3] and runs in $O(n(n + m))$ time rather than $O(n^3)$.

The paper is organized as follows. Background definitions and facts about trapezoid graphs are presented in Section 2, followed by the introduction of Augmentation in Section 3 that adds four new vertices for each vertex of the given graph $G$. Once a graph has been augmented, it is then split (in Section 4), whereby each vertex of the original graph $G$ is replaced with two new vertices. In Section 5, the notion of “$T$-orienting” is introduced which plays a key role in the trapezoid recognition algorithm presented in Section 6. Section 6 also contains the analysis of the running time of this algorithm, followed by concluding remarks in Section 7.

2 Trapezoid graphs and representations

In this section we investigate several properties of trapezoid graphs and their representations. In particular, we define the notion of a standard trapezoid representation with respect to a specific vertex. These properties of trapezoid graphs, as well as the notion of a standard trapezoid representation will then be used for our trapezoid graph recognition algorithm.

Let $R$ be a trapezoid representation of a trapezoid graph $G = (V, E)$, where for any vertex $u \in V$, the trapezoid corresponding to $u$ in $R$ is denoted by $T_u$. Since trapezoid graphs are also cocomparability graphs (there is a transitive orientation of the complement) [6], we can define the partial order $(V, \ll_R)$, such that $u \ll_R v$, or $T_u \ll_R T_v$, if and only if $uv \notin E$ and $T_u$ lies completely to the left of the left of $T_v$ in $R$. In a given trapezoid representation $R$ of a trapezoid graph $G$, we denote by $l(T_u)$ and $r(T_u)$ the left and the right line of $T_u$ in $R$, respectively. Similarly, we use the relation $\ll_R$ for the lines $l(T_u)$ and $r(T_u)$, e.g. $l(T_u) \ll_R r(T_u)$ means that the line $l(T_u)$ lies to the left of the line $r(T_u)$ in $R$. Moreover, if the trapezoids of all vertices of a subset $S \subseteq V$ lie completely to the left (resp. right) of the trapezoid $T_u$ in $R$, we write $R(S) \ll_R T_u$ (resp. $T_u \ll_R R(S)$). Note that there are several trapezoid representations of a particular trapezoid graph $G$. Given one such representation $R$, we can obtain another one $R'$ by vertical axis flipping of $R$, i.e. $R'$ is the mirror image of $R$ along an imaginary line
perpendicular to $L_1$ and $L_2$. In the rest of the paper, given a trapezoid representation $R$, we will use extensively this operation of vertical axis splitting of $R$.

In an arbitrary graph $G = (V, E)$, let $u \in V$ and $U \subseteq V$. Then, $N(u) = \{v \in V : uv \in E\}$ is the set of adjacent vertices of $u$ in $G$, $N[u] = N(u) \cup \{u\}$, and $N(U) = \bigcup_{u \in U} N(u) \setminus U$. If $N(U) \subseteq N(W)$ for two vertex subsets $U$ and $W$, then $U$ is said to be neighborhood dominated by $W$. The relationship of neighborhood domination is clearly transitive. Let $C_1, C_2, \ldots, C_\omega$ be the connected components of $G \setminus N[u]$ and $V_i = V(C_i), i = 1, 2, \ldots, \omega$. For simplicity of the presentation, we will identify in the sequel the component $C_i$ and its vertex set $V_i, i = 1, 2, \ldots, \omega$. For $i = 1, 2, \ldots, \omega$, the neighborhood domination closure of $V_i$ with respect to $u$ is the set $D_u(V_i) = \{V_p : N(V_p) \subseteq N(V_i), p = 1, 2, \ldots, \omega\}$ of connected components of $G \setminus N[u]$. The closure complement of the neighborhood domination closure $D_u(V_i)$ is the set $D_u^*(V_i) = \{V_1, V_2, \ldots, V_\omega\} \setminus D_u(V_i)$.

For a subset $S \subseteq \{V_1, V_2, \ldots, V_\omega\}$, a component $V_i$ of $S$ is called maximal, if there is no component $V_j \in S$, such that $(N(V_j) \subseteq N(V_i))$. Furthermore, we denote by $V(S)$ the vertices of $G$ that belong to the components of $S$, i.e. $V(S) = \cup_{V \in S} V$. A connected component $V_i$ of $G \setminus N[u]$ is called a master component of $u$, if $V_i$ is a maximal component of $\{V_1, V_2, \ldots, V_\omega\}$.

**Lemma 1** Let $G$ be a simple graph, let $u$ be a vertex of $G$, and let $V_1, V_2, \ldots, V_\omega, \omega \geq 1$, be the connected components of $G \setminus N[u]$. If $V_i$ is a master component of $u$, such that $D_u^*(V_i) \neq \emptyset$, then $D_u^*(V_j) \neq \emptyset$ for every component $V_j \in \{V_1, V_2, \ldots, V_\omega\}$.

**Proof.** Since $D_u^*(V_i) \neq \emptyset$, it follows that $D_u(V_i) \subseteq \{V_1, V_2, \ldots, V_\omega\}$. Suppose that there exists a component $V_j \in \{V_1, V_2, \ldots, V_\omega\} \setminus \{V_i\}$, such that $D_u(V_j) = \emptyset$. Then, $D_u(V_i) \subseteq D_u(V_j) = \{V_1, V_2, \ldots, V_\omega\}$, which is a contradiction, since $V_i$ is a master component of $u$. Thus, $D_u^*(V_j) \neq \emptyset$ for every component $V_j \in \{V_1, V_2, \ldots, V_\omega\}$. ■

The following two lemmas will be used in our analysis below.

**Lemma 2** Let $R$ be a trapezoid representation of the trapezoid graph $G$, and let $V_i$ be a master component of $u$, such that $R(V_i) \ll R(T_u)$. Then, $T_u \ll R(V_j)$ for every component $V_j \in D_u^*(V_i)$.

**Proof.** Suppose otherwise that $R(V_j) \ll R(T_u)$, for some $V_j \in D_u^*(V_i)$. We note that if $V_j, V_k$ are two arbitrary distinct connected components of $G \setminus N[u]$, then $R(V_j)$ and $R(V_k)$ do not overlap. First consider the case where $R(V_j) \ll R(V_k) \ll R(T_u)$. Then, since $V_i$ lies between $V_j$ and $T_u$ in $R$, all trapezoids that intersect with $T_u$ and $V_j$ must also intersect with $V_i$. Thus, $N(V_j) \subseteq N(V_i)$ in $G$, i.e. $V_j \in D_u(V_i)$, which is a contradiction, since $V_j \in D_u^*(V_i)$. Consider now the case, where $R(V_j) \ll R(T_u) \ll R(V_k)$. Then, we obtain similarly that $N(V_j) \subseteq N(V_k)$ in $G$, and thus, $N(V_i) = N(V_j)$, since $V_i$ is a master component of $u$. However, since $V_j \in D_u^*(V_i)$, it follows that $N(V_j) \not\subseteq N(V_i)$, which is a contradiction. Thus, $T_u \ll R(V_j)$ for any component $V_j$ of $D_u^*(V_i)$. ■

We caution the reader that $D_u^*(V_i) = \emptyset$ does not mean that there is a trapezoid representation $R$, such that all connected components of $G \setminus N[u]$ lie on the same side of $T_u$ in $R$. To see this, consider the trapezoid graph $G$ of Figure 1. In this example, the connected components of $G \setminus N[u]$ are $V_1 = \{v_1\}$, $V_2 = \{v_2\}$, and $V_3 = \{v_3\}$. Then, $V_2$ is a master component of $u$, since $N(V_1) = \{u_1\}$, $N(V_2) = \{u_1, u_2\}$, and $N(V_3) = \{u_2\}$. Now, $D_u(V_2) = \{V_1, V_2, V_3\}$ and $D_u^*(V_2) = \emptyset$, while $V_1$ and $V_3$ must lie on opposite sides of $T_u$ in every trapezoid representation of $G$.

**Lemma 3** Let $R$ be a trapezoid representation of the trapezoid graph $G$. Let $V_i$ be a master component of $u$ and let $V_j$ be a maximal component of $D_u^*(V_i)$. Then, $N(V_j) = N(V(D_u^*(V_i)))$. 

3
Figure 1: (a) A trapezoid graph $G$ and (b) a trapezoid representation of $G$.

**Proof.** By possibly performing a vertical axis flipping of $R$, we may assume without loss of generality that $R(V_i) \ll R(T_u)$. Then, Lemma 2 implies that $T_u \ll R(D^*_u(V_i))$, i.e. that the trapezoids of every component $V_k \in D^*_u(V_i)$ lie to the right of $T_u$ in $R$. Now let $V_k$ be the leftmost connected component of $G \setminus N[u]$ in $R$, which lies to the right of $T_u$ in $R$. That is, for every other component $V_{k'} \neq V_k$ of $G \setminus N[u]$ that lies to the right of $T_u$ in $R$, we have $T_{k'} \ll R(T_u)$ for all trapezoids $T_x$ and $T_{x'}$ of $V_k$ and $V_{k'}$, respectively. It is easy to see that $N(V_i) \subseteq N(V_k)$, for every other connected component $V_k$ of $G \setminus N[u]$ to the right of $T_u$ in $R$. Suppose that $V_k \in D_u(V_i)$. Then, $N(V_k) \subseteq N(V_i)$, and thus, $N(V_i) \subseteq N(V_k)$ for every component $V_k$ of $G \setminus N[u]$ to the right of $T_u$ in $R$. It follows that $V_k \subseteq D_u(V_i)$ for all these components $V_k$, which is a contradiction, since in particular $V_k \subseteq D^*_u(V_i)$ by the assumption. Thus, $V_k \in D^*_u(V_i)$. Since $T_u \ll R(D(V_k) \ll R(D(V_i))$ for every connected component $V_k \neq V_k$ of $G \setminus N[u]$ to the right of $T_u$ in $R$, it is easy to see that $N(V_i) \subseteq N(V_k)$, for all such components $V_k$. Thus, $V_k$ is a maximal component of $D^*_u(V_i)$, i.e. $N(V_k) = N(V(D^*_u(V_i)))$. Finally, since $V_k$ is also a maximal component of $D^*_u(V_i)$, it follows that $N(V_j) = N(V_k)$, and thus, $N(V_j) = N(V(D^*_u(V_i)))$. This proves the lemma. \hfill \qed

Let $N_0(u) = \{v \in N(u) : N(v) \subseteq N[u]\}$ be the set of neighbors of $u$ that are adjacent only to neighbors of $u$ and to $u$ itself. If $\omega = 0$, i.e. if $V = N[u]$, then let $N_1(u) = N_2(u) = N_{12}(u) = \emptyset$. Suppose for the following two definitions that $\omega \geq 1$. In the rest of the paper, we say that a vertex $v$ is "adjacent to a connected component $V_i$ of $G \setminus N[u]$" if $v$ is adjacent to at least one vertex of $V_i$.

**Definition 1** Let $u$ be a vertex of a graph $G$. Let $V_i$ be a master component of $u$, such that $D^*_u(V_i) \neq \emptyset$. Then, the vertices of $N(u) \setminus N_0(u)$ are partitioned into three possibly empty sets:

1. $N_1(u)$: vertices adjacent to $V_i$ and not to $D^*_u(V_i)$.
2. $N_2(u)$: vertices adjacent to $D^*_u(V_i)$ and not to $V_i$.
3. $N_{12}(u)$: vertices adjacent to both $V_i$ and $D^*_u(V_i)$.

Note that every neighbor $w \in N(u) \setminus N_0(u)$ is adjacent to $D_u(V_i)$ or to $D^*_u(V_i)$. Furthermore, every $w \in N(u) \setminus N_0(u)$ that is adjacent to $D_u(V_i)$ is also adjacent to $V_i$, and thus, in Definition 1, the sets $N_1(u)$, $N_2(u)$ and $N_{12}(u)$ indeed partition the set $N(u) \setminus N_0(u)$.

**Definition 2** Let $u$ be a vertex of a graph $G$. Let $V_i$ be a master component of $u$, such that $D^*_u(V_i) = \emptyset$. Then, $N_2(u) = \emptyset$, and the vertices of $N(u) \setminus N_0(u)$ are partitioned into two possibly empty sets:

1. $N_1(u) = \{v \in N(V_i) : N_0(u) \nsubseteq N(v)\}$. 

4
2. \( N_{12}(u) = \{v \in N(V_i) : N_0(u) \subseteq N(v)\} \).

Note that, if \( D_u^*(V_i) = \emptyset \), i.e. if \( D_u(V_i) = \{V_1, V_2, \ldots , V_\omega\} \), then every neighbor \( w \in N(u) \setminus N_0(u) \) is also a neighbor of the component \( V_i \). Thus, in Definition 2, the sets \( N_1(u) \) and \( N_{12}(u) \) indeed partition the set \( N(u) \setminus N_0(u) \). Henceforth, any reference to the sets \( N_1(u), N_2(u), N_{12}(u) \) is understood to be with respect to some master component \( V_i \), cf. Definitions 1 and 2.

**Lemma 4** Let \( G = (V,E) \) be a graph, where \(|V| = n\) and \(|E| = m\), and let \( u \in V \). Then a master component \( V_i \) of \( u \), as well as the related sets \( N_0(u), N_1(u), N_2(u) \) and \( N_{12}(u) \) can be computed in \( O(n + m) \) time.

**Proof.** Let \( V = \{v_1, v_2, \ldots , v_n\} \) be an enumeration of the vertices of \( G \), such that \( v_1 = u \) and the neighbors of \( u \) are stored in the first \( \text{deg}(u) \) positions after \( v_1 \). That is, \( v_1, v_2, \ldots , v_n \) in the list. After appropriate initializations, we will examine each connected component in order \( V_1, V_2, \ldots , V_\omega \) and the adjacency list for each vertex in the given connected component. Suppose we are examining edge \( v_k v_k \) where \( v_k \in V_j, 1 \leq j \leq \omega \). If \( k > \text{deg}(u) + 1 \) (i.e. \( v_k \notin N(u) \)), then ignore this edge; otherwise look at \( v_k \)’s list. If the last element of this list is not \( j \), then add \( v_k \) to \( N(V_j) \), increment \( |N(V_j)| \), add \( j \) to \( v_k \)’s list and increment \( \text{len}(v_k) \). Note that all of these operations can be charged to edges of \( G \), and thus our computation is bounded by \( O(n + m) \).

To find a master component \( V_i \) it suffices to choose a \( V_i \) that maximizes \(|N(V_j)|, 1 \leq j \leq \omega \). Furthermore, \( N_0(u) = \{v \in N(u) : \text{len}(v) = 0\} \). These sets can be computed in \( O(n) \) time.

We now compute \( D_u^*(V_i) \), the indices of connected components not in \( D_u(V_i) \). First we create a 0-1 vector of length \(|N(u)|\) to store the membership of \( N(V_i) \) and allow constant time determination of membership. Now examine all connected components \( V_j \) other than \( V_i \) and scan the \( N(V_j) \) list. If at any time an element is encountered that is not in \( N(V_i) \) then stop the scan of the \( N(V_j) \) list and place such a \( j \) in \( D_u^*(V_i) \). Again, by charging edges, this can be done in \( O(n + m) \) time.

The set \( N(D_u^*(V_i)) = \bigcup_{j \in D_u^*(V_i)} N(V_j) \) can now be computed in \( O(n + m) \) time by scanning all components whose indices are in \( D_u^*(V_i) \) and forming a 0-1 vector of length \(|N(u)|\) to store the membership of this set. In the case where \( D_u^*(V_i) \neq \emptyset \), we can now compute the sets \( N_1(u), N_2(u), \text{and } N_{12}(u) \) in \( O(n) \) time, since

\[
N_1(u) = N(V_i) \setminus N(D_u^*(V_i)) \\
N_2(u) = N(D_u^*(V_i)) \setminus N(V_i) \\
N_{12}(u) = N(V_i) \cap N(D_u^*(V_i))
\]

by Definition 1. Now consider the case where \( D_u^*(V_i) = \emptyset \). Look at all edges \( v_j v_k \), where \( v_j \in N_0(u) \) and for each such edge (except \( v_j u \)), increment \( d(v_k) \), initialized to 0 (note that \( d(v_k) \) stores \(|N(v_k) \cap N_0(u)|\) ). According to Definition 2,

\[
N_{12}(u) = \{v_k \in N(u) : d(v_k) = |N_0(u)|\} \\
N_1(u) = N(V_i) \setminus N_{12}(u) \\
N_2(u) = \emptyset.
\]
This can all be done in $O(n + m)$, thereby completing the lemma.

Now, we define the notion of a standard trapezoid representation with respect to a particular vertex of a trapezoid graph, which is crucial for our recognition algorithm.

**Definition 3** Let $G$ be a trapezoid graph and let $u$ be a vertex of $G$. A trapezoid representation $R$ of $G$ is called standard with respect to $u$, if:

1. the line $l(T_u)$ intersects exactly with the trapezoids of $N_1(u) \cup N_{12}(u)$ in $R$, and
2. the line $r(T_u)$ intersects exactly with the trapezoids of $N_2(u) \cup N_{12}(u)$ in $R$.

**Lemma 5** Let $G$ be a trapezoid graph, and let $u$ be a vertex of $G$. Then, there exists a standard trapezoid representation of $G$ with respect to $u$.

**Proof.** Let $R$ be a trapezoid representation of $G$. Let $V_1, V_2, \ldots, V_ω$ be the connected components of $G \setminus N[u]$. If $ω = 0$, then $V(G) = N[u]$ and $N_1(u) = N_2(u) = N_{12}(u) = \emptyset$. In this case, we can move in $R$ the left line $l(T_u)$ (resp. the right line $r(T_u)$) to the left (resp. right), such that all endpoints of the trapezoids corresponding to vertices of $G \setminus \{u\}$ lie between $l(T_u)$ and $r(T_u)$. Then, the resulting trapezoid representation $R'$ satisfies both conditions of Definition 3, and thus, $R'$ is a standard trapezoid representation of $G$ with respect to $u$. Suppose now that $ω \geq 1$, and let $V_i$ be a master component of $u$. Furthermore let $N_ω(u_k)$, $X \in \{1, 2, 12\}$, be the sets defined in Definitions 1 and 2 corresponding to the master component $V_i$. By possibly performing a vertical axis flipping of $R$, we may assume without loss of generality that $R(V_i) \ll_R T_u$. Denote by $D_1(u, R)$ (resp. $D_2(u, R)$) the set of trapezoids that lie to the left (resp. right) of $T_u$ in $R$.

Now consider any connected component $V_k$ of $G \setminus N[u]$, such that $R(V_k) \ll_R R(V_k) \ll_R T_u$. We will prove that $N(V_i) = N(V_k)$. Indeed, since $V_k$ lies between $V_i$ and $T_u$ in $R$, all trapezoids that intersect with $T_u$ and $V_i$, must also intersect with $V_k$, and thus, $N(V_i) \subseteq N(V_k)$. Now, $N(V_i) = N(V_k)$, since $V_i$ is a master component of $u$, i.e. we may assume without loss of generality that $V_i$ is the rightmost component of $D_1(u, R)$. Thus, $N_1(u) \cup N_{12}(u)$ is exactly the set of neighbors of $u$, that are adjacent to some trapezoids of $D_1(u, R)$.

Denote for the purposes of the proof by $p_v$ and $q_v$ the endpoints on $L_1$ and $L_2$, respectively, of the left line $l(T_x)$ of an arbitrary trapezoid $T_x$ in $R$. Suppose that $N_0(u) \cup N_2(u) \neq \emptyset$. Let $p_v$ and $q_v$ be the leftmost endpoints on $L_1$ and $L_2$, respectively, of the trapezoids of $N_0(u) \cup N_2(u)$, and suppose that $p_v < p_u$ and $q_w < q_a$. Let $v$ and $w$ be the vertices of $N_0(u) \cup N_2(u)$ that realize the endpoints $p_v$ and $q_w$, respectively. Note that, possibly, $v = w$. Then, all vertices $x$, for which $T_x$ has an endpoint between $p_v$ and $p_u$ on $L_1$ (resp. between $q_u$ and $q_a$ on $L_2$) are adjacent to $u$. Indeed, suppose otherwise that $T_x \cap T_u = \emptyset$, for such a vertex $x$. Then, since $T_v \cap T_u \neq \emptyset$, it follows that $T_x \cap T_v = \emptyset$ (resp. $T_x \cap T_w = \emptyset$). However, since $T_x \cap T_v = \emptyset$, and since $T_x$ has an endpoint to the left of $T_u$ in $R$, it follows that $T_x \ll_R T_u$, i.e. $T_x \in D_1(u, R)$, and thus, $v \in N_1(u) \cup N_{12}(u)$ (resp. $w \in N_1(u) \cup N_{12}(u)$), which is a contradiction.

We now construct a trapezoid representation $R'$ of $G$ from $R$, by moving both endpoints $p_u$ and $q_u$ of $l(T_u)$ directly before $p_v$ and $q_v$ on $L_1$ and $L_2$, respectively. Then, all trapezoids that correspond to vertices of $N_0(u) \cup N_2(u)$ lie to the right of the line $l(T_u)$ in $R'$. Since $u$ is adjacent to all vertices $x$, for which $T_x$ has an endpoint between $p_v$ and $p_u$ on $L_1$, or between $q_w$ and $q_a$ on $L_2$ in $R$, the resulting representation $R'$ is a trapezoid representation of $G$. Furthermore, since the trapezoids of $N_1(u) \cup N_{12}(u)$ intersect with $T_u$ and with some trapezoids of $D_1(u, R)$, they must intersect with the line $l(T_u)$, and thus, the first condition of Definition 3 is satisfied.

Note that, in the case where $p_v > p_u$ (resp. $q_v > q_a$), we do not move the point $p_u$ (resp. $q_a$) in the above construction, while in the case where $N_0(u) \cup N_2(u) = \emptyset$, we define $R' = R$. An
example of the construction of $R'$ for the case where $D^*_u(V_i) \neq \emptyset$ is given in Figure 2 (for the case where $D^*_0(V_i) = \emptyset$, the construction of $R'$ is the same). In this example, $v \in N_0(u)$, $w \in N_2(u)$, $z \in N_1(u)$, and $y \in N_{12}(u)$.

Recall that $R'$ satisfies the first condition of Definition 3. In the following, we construct another trapezoid representation $R''$ (resp. $R'''$) from $R'$ in the case where $D^*_u(V_i) \neq \emptyset$ (resp. $D^*_0(V_i) = \emptyset$), which also satisfies the second condition of Definition 3. Thus, $R''$ (resp. $R'''$) is a standard trapezoid representation of $G$ with respect to $u$.

Suppose first that $D^*_u(V_i) \neq \emptyset$, and let $V_j$ be a maximal component of $D^*_u(V_i)$. Due to Lemma 3, $N(V_j) = N(D^*_u(V_i))$, i.e. $N_2(u) \cup N_{12}(u)$ is exactly the set of neighbors of $u$, that are adjacent to some trapezoids of $D_2(u, R)$. If $R'$ is not a standard trapezoid representation with respect to $u$, then we move (similarly to the construction of $R'$ from $R$) the right line $r(T_u)$ of $T_u$ to the right, thus obtaining a trapezoid representation $R''$ of $G$, in which the second condition of Definition 3 is satisfied. Since, during the construction of $R''$ by $R'$, only the line $r(T_u)$ is possibly moved to the right, the first condition of Definition 3 is satisfied for $R''$ as well. Thus, $R''$ is a standard representation of $G$ with respect to $u$.

Suppose now that $D^*_u(V_i) = \emptyset$. Then, $N_2(u) = \emptyset$ by Definition 2. Similarly to the construction of the trapezoid representation $R'$ from $R$, we move in $R'$ the right line $r(T_u)$ possibly to the right, directly after the endpoints of the trapezoids of $N_0(u)$ on $L_1$ and $L_2$. The resulting trapezoid representation $R''$ of $G$ satisfies the first condition of Definition 3, while all trapezoids that correspond to vertices of $N_0(u)$ lie to the left of the line $r(T_u)$ in $R''$. Since $R''(V_i) \ll R'' T_u$, and due to Definition 2, for every vertex $v \in N_1(u)$ there exists at least one vertex $w \in N_0(u)$, such that $T_v \ll R'' T_w$. Thus, since $R''(N_0(u)) \ll R'' r(T_u)$, it follows that $T_v \ll R'' r(T_u)$ for every vertex $v \in N_1(u)$.

Furthermore, due to Definition 2, $N_0(u) \subseteq N(v)$ for every vertex $v \in N_{12}(u)$. Now consider a vertex $v \in N_{12}(u)$ and a vertex $z \in N(V_i)$, such that $T_v \ll R'' T_z$. Suppose, for the sake of contradiction, that $N_0(u) \not\subseteq N(z)$. Then, since $R''(V_i) \ll R'' T_u$, there exists a vertex $w \in N_0(u)$, such that $T_z \ll R'' T_w$. Thus, since $T_v \ll R'' T_w$, it follows that $T_v \ll R'' T_w$. This is a contradiction, since every vertex $v \in N_{12}(u)$ is adjacent to all vertices $w \in N_0(u)$. Thus, $N_0(u) \subseteq N(z)$, i.e. $z \in N_{12}(u)$. Therefore, we can move the endpoints of the trapezoids of
$N_{12}(u)$ appropriately to the right, such that they all intersect the line $r(T_u)$, and such that no new adjacency is introduced and all old adjacencies are preserved. The resulting trapezoid representation $R''$ of $G$ satisfies both conditions of Definition 3, and thus, $R''$ is a standard representation of $G$ with respect to $u$. An example of the construction of $R''$ from $R'$ is given in Figure 3. In this example, $w, w' \in N_0(u), x \in N_1(u)$, and $v, z \in N_{12}(u)$.

3 An augmenting algorithm

In this section we present Algorithm Augment-All, which takes as input an arbitrary undirected graph $G$ with $n$ vertices and augments it to a graph $G^*$ with $5n$ vertices. The constructed graph $G^*$ has the property (see Lemma 11) that for every vertex $u_i, i = 1, 2, \ldots, n$, of the original graph $G$, there exists a master component $V_j$ of $u_i$ in $G^*$ such that $D_{u_i}(V_j) \neq \emptyset$. The graph $G^*$ will serve as the basis for the vertex splitting described in the next section. We now define the augmented graph $G^*(u_i)$ for an arbitrary graph $G$ and a vertex $u_i$ of $G$.

**Definition 4** Let $u_i$ be a vertex of a graph $G$. The augmented graph $G^*(u_i)$ of $G$ with respect to $u_i$ is defined as follows:

1. $V(G^*(u_i)) = V(G) \cup \{u_{i,1}, u_{i,2}, u_{i,3}, u_{i,4}\}$,
2. $E(G^*(u_i)) = E(G) \cup \{u_{i,1}u_{i,1}, u_{i,1}u_{i,2}, u_{i,1}u_{i,3}, u_{i,1}u_{i,4}\} \cup \{u_{i,1}x, u_{i,1}x : x \in N_1(u_i) \cup N_{12}(u_i)\} \cup \{u_{i,3}x, u_{i,4}x : x \in N_2(u_i) \cup N_{12}(u_i)\}$.

The vertices $u_{i,1}, u_{i,2}, u_{i,3}, u_{i,4}$ are the augmenting vertices of $u_i$.

Note that, by Definition 4, $\{u_{i,2}\}$ and $\{u_{i,4}\}$ are two connected components of $G^*(u_i) \setminus N_{G^*(u_i)}[u_i]$.

**Lemma 6** Let $G$ be an arbitrary graph and let $u_i$ be a vertex of $G$. The graph $G^*(u_i)$ is trapezoid if and only if $G$ is trapezoid.
Proof. Suppose that $G^*(u_i)$ is a trapezoid graph. Then, since $G$ is an induced subgraph of $G^*(u_i)$, and since the trapezoid property is hereditary, it follows that $G$ is a trapezoid graph as well.

Now suppose that $G$ is a trapezoid graph. Then, by Lemma 5 there exists a standard trapezoid representation $R$ of $G$ with respect to $u_i$. Therefore, it follows by Definition 3 that the left line $l(T_{u_i})$ of $T_{u_i}$ intersects exactly with the trapezoids of $N_1(u_i) \cup N_{12}(u_i)$ in $R$, while the right line $r(T_{u_i})$ of $T_{u_i}$ intersects exactly with the trapezoids of $N_2(u_i) \cup N_{12}(u_i)$ in $R$. We can add to $R$ four trivial trapezoids (i.e., lines) $l(u_{i,1})$, $l(u_{i,2})$, $l(u_{i,3})$ and $l(u_{i,4})$, as follows: $l(u_{i,2})$ (resp. $l(u_{i,4})$) is parallel to $l(T_{u_i})$ (resp. to $r(T_{u_i})$) to its left (resp. right), and lies arbitrarily close to $l(T_{u_i})$ (resp. to $r(T_{u_i})$). Furthermore, $l(u_{i,1})$ (resp. $l(u_{i,3})$) intersects both $l(T_{u_i})$ and $l(u_{i,2})$ (resp. both $r(T_{u_i})$ and $l(u_{i,4})$), and lies arbitrarily close to them.

An example of this construction is illustrated in Figure 4. Note that, in the resulting trapezoid representation, the line $l(u_{i,2})$ (resp. the line $l(u_{i,4})$) intersects with exactly the same trapezoids as the left line $l(T_{u_i})$ (resp. the right line $r(T_{u_i})$) of $T_{u_i}$. That is, $l(u_{i,2})$ (resp. $l(u_{i,4})$) intersects with $l(u_{i,1})$ (resp. with $l(u_{i,3})$), as well as with the trapezoids of $N_1(u_i) \cup N_{12}(u_i)$ (resp. with the trapezoids of $N_2(u_i) \cup N_{12}(u_i)$). Furthermore, recall by construction that the line $l(u_{i,1})$ (resp. $l(u_{i,3})$) lies arbitrarily close to the lines $l(T_{u_i})$ and $l(u_{i,2})$ (resp. to the lines $r(T_{u_i})$ and $l(u_{i,4})$). Therefore, in the resulting trapezoid representation, $l(u_{i,1})$ intersects with $l(T_{u_i})$ and $l(u_{i,2})$, as well as with the trapezoids of $N_1(u_i) \cup N_{12}(u_i)$. Similarly, $l(u_{i,3})$ intersects with $r(T_{u_i})$ and $l(u_{i,4})$, as well as with the trapezoids of $N_2(u_i) \cup N_{12}(u_i)$. Thus, it follows by Definition 4 that the resulting representation is a trapezoid representation of $G^*(u_i)$, and thus $G^*(u_i)$ is a trapezoid graph. This completes the proof of the lemma.

![Figure 4: The augmentation of the vertex $u_i$ of $G$ in the augmented graph $G^*(u_i)$](image)

**Lemma 7** Let $u_i$ be a vertex of a graph $G$. Then, $\{u_{i,2}\}$ and $\{u_{i,4}\}$ are master components of $u_i$ in $G^*(u_i)$. Furthermore, $D^*_{u_i}(\{u_{i,2}\}) \neq \emptyset$ and $D^*_{u_i}(\{u_{i,4}\}) \neq \emptyset$ in $G^*(u_i)$.

**Proof.** For simplicity reasons, in the proof we will denote the neighborhood $N_{G^*(u_i)}(U)$ of a vertex set $U$ in $G^*(u_i)$ by $N(U)$. Let $V_1, V_2, \ldots, V_\omega$ be the connected components of $G \setminus N_G[u_i]$. The connected components of $G^*(u_i) \setminus N[u_i]$ are $\{u_{i,2}\}, \{u_{i,4}\}, V_1, V_2, \ldots, V_\omega$. Suppose that $\{u_{i,2}\}$ (resp. $\{u_{i,4}\}$) is not a master component of $u_i$ in $G^*(u_i)$. Then, there exists a connected component $V_0$ of $G^*(u_i) \setminus N[u_i]$, such that $N(\{u_{i,2}\}) \subset N(V_0)$ (resp. $N(\{u_{i,4}\}) \subset N(V_0)$), and thus, $u_{i,1} \in N(V_0)$ (resp. $u_{i,3} \in N(V_0)$). By the construction of $G^*(u_i)$, there exists no connected component $V_0 \in \{V_1, V_2, \ldots, V_\omega, \{u_{i,2}\}\}$, such that $u_{i,1} \in N(V_0)$. Similarly, there exists no connected component $V_0 \in \{V_1, V_2, \ldots, V_\omega, \{u_{i,4}\}\}$, such that $u_{i,3} \in N(V_0)$, which is a contradiction. Thus, $\{u_{i,2}\}$ and $\{u_{i,4}\}$ are master components of $u_i$ in $G^*(u_i)$.

Finally, since $u_{i,1} \in N(\{u_{i,2}\}) \cap N(\{u_{i,4}\})$ and $u_{i,3} \in N(\{u_{i,4}\}) \cap N(\{u_{i,2}\})$, it follows that $\{u_{i,4}\} \in D^*_{u_i}(\{u_{i,2}\}) \neq \emptyset$ and that $\{u_{i,2}\} \in D^*_{u_i}(\{u_{i,4}\}) \neq \emptyset$ in $G^*(u_i)$. This proves the lemma.
After augmenting a vertex \( u_i \) of \( G \), obtaining the graph \( G^*(u_i) \), we can continue by augmenting an arbitrary vertex of \( V(G) \setminus \{u_i\} \) in \( G^*(u_i) \). This process can be repeated \(|V(G)|\) times, until all vertices of \( V(G) \) have been augmented, as presented in Algorithm Augment-All. The resulting graph \( G^* \) has \( 5|V(G)| \) vertices, since at every iteration of Algorithm Augment-All we add four new augmenting vertices. Note that in this algorithm, we choose an arbitrary ordering by which we augment the vertices of \( V \). We now show that in any iteration of Algorithm Augment-All after the first one, if a vertex is made adjacent to \( u_{i,2} \) it is also made adjacent to \( u_{i,1} \); furthermore, if a vertex is made adjacent to \( u_{i,1} \) it is also made adjacent to \( u_i \) and to \( u_{i,2} \).

**Algorithm 1 Augment-All**

**Input:** A graph \( G \) with vertex set \( V = \{u_1, u_2, \ldots, u_n\} \)

**Output:** Augment every vertex of \( V \) to produce \( G^* \)

1. \( G_0 \leftarrow G \)
2. for \( i = 1 \) to \( n \) do
3. \( G_i \leftarrow G_{i-1}^*(u_i) \) \{ \( G_i \) is obtained by augmenting the vertex \( u_i \) of \( G_{i-1} \) \}
4. \( G^* \leftarrow G_n \)
5. return \( G^* \)

At every step of Algorithm Augment-All, the graph \( G_i \) has, by Definition 4, four more vertices \( u_{i,1}, u_{i,2}, u_{i,3}, u_{i,4} \) than the previous graph \( G_{i-1} \). Each of these four new vertices has at most \(|N_{G_{i-1}}(u_i)| + 2\) neighbors in \( G_i \), while \( u_i \) has exactly \(|N_{G_{i-1}}(u_i)| + 2\) neighbors in \( G_i \). Thus, in the graph \( G^* = G_n \) returned by Algorithm Augment-All, every vertex \( u_i \) of the input graph \( G \) has been replaced by an induced path \( (u_{i,2}, u_{i,1}, u_i, u_{i,3, u_{i,4}}) \), while every edge \( u_iu_j \) of the input graph \( G \) has been replaced by at most \( 5 \cdot 5 = 25\) edges, i.e. at most all possible edges with one endpoint in \( \{u_i, u_{i,1}, u_{i,2}, u_{i,3, u_{i,4}}\} \) and one endpoint in \( \{u_j, u_{j,1}, u_{j,2}, u_{j,3, u_{j,4}}\} \). Summarizing, the graph \( G^* = G_n \) returned by Algorithm Augment-All has \( O(n) \) vertices and \( O(m) \) edges, and thus the same holds for every intermediate graph \( G_i, i = 1, 2, \ldots, n \). Therefore, since by Lemma 4 the sets \( N_0, N_1, N_2, \) and \( N_{12} \) for a graph with \( n \) vertices and \( m \) edges can be computed in \( O(n + m) \) time, the next lemma follows.

**Lemma 8** Algorithm 1 runs in \( O(n(n + m)) \) time.

The following corollary easily follows by repeatedly applying Lemma 6.

**Corollary 1** The graph \( G^* \) constructed by Algorithm Augment-All is trapezoid if and only if the input graph \( G \) is trapezoid.

We now show that in any iteration of Algorithm Augment-All after the \( i \)th one, if a vertex is made adjacent to \( u_{i,2} \) it is also made adjacent to \( u_{i,1} \); furthermore, if a vertex is made adjacent to \( u_{i,1} \) it is also made adjacent to \( u_i \) and to \( u_{i,2} \).

**Lemma 9** Let \( u_i \) be a vertex of a graph \( G \), and let \( G_k \) be the graph constructed at the \( k \)th step of Algorithm Augment-All, where \( k \geq i \), (i.e. after augmenting vertex \( u_i \)). Then,

- \( N_{G_k}[u_{i,2}] = N_{G_k}[u_{i,1}] \setminus \{u_i\} \)
- \( N_{G_k}[u_{i,1}] \setminus \{u_{i,2}\} \subseteq N_{G_k}[u_i] \).
Therefore, due to the construction of the augmented graph $G_k$ from $G_{k-1}$ at the kth step of Algorithm Augment-All. Let $V_j$ be a master component of $u_k$ in $G_{k-1}$, and let $N_X(u_k)$, $X = \{1, 2, 12\}$, be the sets defined in Definitions 1 and 2 corresponding to the master component $V_j$.

Case 1. $D^*_u(V_j) \neq \emptyset$ in $G_{k-1}$ (cf. Definition 1). Suppose that $u_{i,2}$ is adjacent in $G_k$ to $u_{k,1}$ and $u_{k,2}$ (resp. $u_{k,3}$ and $u_{k,4}$), i.e. that $u_{i,2} \in N_1(u_k) \cup N_2(u_k)$ (resp. $u_{i,2} \in N_2(u_k) \cup N_1(u_k)$) in $G_{k-1}$.

Then, $u_{i,2}$ is adjacent in $G_{k-1}$ to $u_k$ and to at least one vertex $v$ that belongs to a connected component of $G_{k-1} \setminus N_{G_{k-1}}[u_k]$, i.e. $u_k, v \in N_{G_{k-1}}(u_{i,2})$. It follows by the induction hypothesis that $u_k, v \in N_{G_{k-1}}[u_1]$, and thus, $u_{i,1} \in N_1(u_k) \cup N_2(u_k)$ (resp. $u_{i,1} \in N_2(u_k) \cup N_1(u_k)$) in $G_{k-1}$. Therefore, $u_{i,1}$ is adjacent in $G_k$ to $u_{k,1}$ and $u_{k,2}$ (resp. $u_{k,3}$ and $u_{k,4}$) as well. Thus, $N_{G_k}[u_{i,2}] \subseteq N_{G_k}[u_{i,1}] \setminus \{u_1\}$.

Now we show that $N_{G_k}[u_{i,1}] \setminus \{u_i\} \subseteq N_{G_k}[u_{i,2}]$. Suppose that $u_{i,1}$ is adjacent in $G_k$ to $u_{k,1}$ and $u_{k,2}$ (resp. $u_{k,3}$ and $u_{k,4}$), i.e. that $u_{i,1} \in N_1(u_k) \cup N_2(u_k)$ (resp. $u_{i,1} \in N_2(u_k) \cup N_1(u_k)$) in $G_{k-1}$. Then, similarly to the previous paragraph, $u_{i,1}$ is adjacent in $G_{k-1}$ to $u_k$ and to at least one vertex $v$ that belongs to a connected component of $G_{k-1} \setminus N_{G_{k-1}}[u_k]$, i.e. $u_k, v \in N_{G_{k-1}}(u_{i,1})$. Since $N_{G_{k-1}}[u_{i,1}] \setminus \{u_{i,2}\} \subseteq N_{G_{k-1}}[u_1]$, and since $u_{i,2} \neq u_k$, it follows that $u_k \in N_{G_{k-1}}(u_{i,2})$. Thus, $u_{i,2} \neq v$, i.e. $u_k, v \in N_{G_{k-1}}[u_{i,1}] \setminus \{u_1\}$. Therefore, it follows by the induction hypothesis that $u_k, v \in N_{G_{k-1}}[u_{i,2}]$, and thus, $u_{i,1} \in N_1(u_k) \cup N_2(u_k)$ (resp. $u_{i,1} \in N_2(u_k) \cup N_1(u_k)$) in $G_{k-1}$. Therefore, $u_{i,2}$ is adjacent in $G_k$ to $u_{k,1}$ and $u_{k,2}$ (resp. $u_{k,3}$ and $u_{k,4}$) as well. Thus, $N_{G_k}[u_{i,1}] \setminus \{u_i\} \subseteq N_{G_k}[u_{i,2}]$. Summarizing, we obtain that $N_{G_k}[u_{i,2}] = N_{G_k}[u_{i,1}] \setminus \{u_i\}$ for the case where $D^*_u(V_j) \neq \emptyset$.

Furthermore, since $u_k, v \in N_{G_{k-1}}[u_{i,2}]$, it follows that $u_{i,2} \notin \{u_k, v\}$. Thus, $u_k, v \in N_{G_k}[u_{i,1}] \setminus \{u_{i,2}\} \subseteq N_{G_k}[u_1]$, and thus, $u_{i,1} \in N_1(u_k) \cup N_2(u_k)$ (resp. $u_{i,1} \in N_2(u_k) \cup N_1(u_k)$) in $G_{k-1}$. Therefore, $u_{i,1}$ is adjacent in $G_k$ to $u_{k,1}$ and $u_{k,2}$ (resp. $u_{k,3}$ and $u_{k,4}$) as well, i.e. $N_{G_k}[u_{i,1}] \setminus \{u_{i,2}\} \subseteq N_{G_k}[u_1]$. This completes the induction step for the case where $D^*_u(V_j) \neq \emptyset$.

Case 2. $D^*_u(V_j) = \emptyset$ in $G_{k-1}$ (cf. Definition 2). Then, $N_2(u_k) = \emptyset$ in $G_{k-1}$. First suppose that $u_{i,2}$ is adjacent in $G_k$ to $u_{k,1}$ and $u_{k,2}$, i.e. $u_{i,2} \in N_1(u_k) \cup N_2(u_k) = N_{G_{k-1}}(u_k) \setminus N_0(u_k)$ in $G_{k-1}$. Then, $u_{i,2}$ is adjacent in $G_{k-1}$ to $u_k$ and to at least one vertex $v$ that belongs to the master component $V_j$ of $u_k$. Thus, since $u_k, v \in N_{G_{k-1}}(u_{i,2})$, it follows by the induction hypothesis that $u_k, v \in N_{G_{k-1}}[u_{i,1}]$, and thus $u_{i,1} \in N_{G_{k-1}}(u_k) \setminus N_0(u_k) = N_1(u_k) \cup N_2(u_k)$ in $G_{k-1}$. Hence, $u_{i,1}$ is adjacent in $G_k$ to $u_{k,1}$ and $u_{k,2}$ as well.

Now suppose that $u_{i,2}$ is adjacent in $G_k$ to $u_{k,3}$ and $u_{k,4}$, i.e. $u_{i,2} \in N_1(u_k) \cup N_2(u_k) \subseteq N_{G_{k-1}}(u_k) \setminus N_0(u_k)$ in $G_{k-1}$. Similarly to the previous paragraph, $u_{i,1} \in N_{G_{k-1}}(u_k) \setminus N_0(u_k) = N_1(u_k) \cup N_2(u_k)$ in $G_{k-1}$ as well. Furthermore, since $u_{i,2} \in N_2(u_k)$, it follows by Definition 2 and by the induction hypothesis that $N_0(u_k) \subseteq N_{G_{k-1}}[u_{i,2}] \subseteq N_{G_{k-1}}[u_{i,1}]$. Since $u_{i,1} \notin N_0(u_k)$, $N_0(u_k) \subseteq N_{G_{k-1}}(u_{i,1})$, and therefore, $u_{i,1}$ is adjacent in $G_k$ to $u_{k,3}$ and $u_{k,4}$ as well. Summarizing, we see that $N_{G_k}[u_{i,2}] \subseteq N_{G_k}[u_{i,1}] \setminus \{u_i\}$.

Suppose that $u_{i,1}$ is adjacent in $G_k$ to $u_{k,1}$ and $u_{k,2}$, i.e. that $u_{i,1} \in N_1(u_k) \cup N_2(u_k)$ in $G_{k-1}$. Then, $u_{i,1}$ is adjacent in $G_{k-1}$ to $u_k$ and to at least one vertex $v$ that belongs to the master component $V_j$ of $u_k$, i.e. $u_k, v \in N_{G_{k-1}}[u_{i,1}]$. Since $N_{G_{k-1}}[u_{i,1}] \setminus \{u_{i,2}\} \subseteq N_{G_{k-1}}[u_1]$, and since $u_{i,2} \neq u_k$, it follows that $u_k \in N_{G_{k-1}}(u_{i,1})$. Thus, $u_{i,1} \neq v$, i.e. $u_k, v \in N_{G_{k-1}}[u_{i,1}] \setminus \{u_1\} = N_{G_{k-1}}[u_{i,2}]$. It follows that $u_{i,2} \in N_{G_{k-1}}(u_k) \setminus N_0(u_k) = N_1(u_k) \cup N_2(u_k)$ in $G_{k-1}$. Hence, $u_{i,2}$ is adjacent in $G_k$ to $u_{k,1}$ and $u_{k,2}$ as well. Furthermore, since $u_k, v \in N_{G_{k-1}}[u_{i,2}]$, it follows that $u_{i,2} \notin \{u_k, v\}$. Thus, $u_k, v \in N_{G_k}[u_{i,1}] \setminus \{u_{i,2}\} \subseteq N_{G_k}[u_1]$, and thus, $u_{i,1} \in N_{G_{k-1}}(u_k) \setminus N_0(u_k) = N_1(u_k) \cup N_2(u_k)$ in $G_{k-1}$. Hence, $u_{i,1}$ is adjacent in $G_k$ to $u_{k,1}$ and $u_{k,2}$ as well.

Now suppose that $u_{i,1}$ is adjacent in $G_k$ to $u_{k,3}$ and $u_{k,4}$, i.e. that $u_{i,1} \in N_2(u_k) \subseteq N_{G_{k-1}}(u_k) \setminus N_0(u_k)$ in $G_{k-1}$. Similarly to the previous paragraph, $u_{i,2}, u_{i,1} \in N_{G_{k-1}}(u_k) \setminus N_0(u_k)$ \setminus N_0(u_k).
Lemma 10 Let $u_i$ be a vertex of a graph $G$, and let $G_k$ be the graph constructed at the $k$th step of Algorithm Augment-All, where $k \geq i$, i.e. after augmenting vertex $u_i$. Then,

- $N_{G_k}[u_{i,4}] = N_{G_k}[u_{i,3}] \setminus \{u_i\}$
- $N_{G_k}[u_{i,3}] \setminus \{u_i, u_{i,4}\} \subseteq N_{G_k}[u_i]$.

We can now obtain the following lemma, which extends Lemma 7.

Lemma 11 Let $u_i$ be a vertex of a graph $G$. Then, $\{u_{i,2}\}$ and $\{u_{i,4}\}$ are master components of $u_i$ in $G^*$. Furthermore, $D_{u_i}^*((u_{i,2})) \neq \emptyset$ and $D_{u_i}^*((u_{i,4})) \neq \emptyset$ in $G^*$.

Proof. Consider the graph $G^* = G_n$ computed by Algorithm Augment-All, and let $u_i$ be a vertex of $G$. For simplicity reasons, in the proof we will denote the neighborhood $N_{G^*}(U)$ of a vertex set $U$ in $G^*$ by $N(U)$. Suppose first that $\{u_{i,2}\}$ (resp. $\{u_{i,4}\}$) is not a connected component of $G^* \setminus N[u_i]$. Then, since $u_{i,2}$ (resp. $u_{i,4}$) is not adjacent to $u_i$ in $G^*$, there must be at least one vertex $v$ of $G^*$, that is adjacent to $u_{i,2}$ (resp. $u_{i,4}$) and not to $u_i$ in $G^*$. However, since $v \notin \{u_{i,2}, u_{i,4}\}$, and since $v \in N[u_{i,2}]$ (resp. $v \in N[u_{i,4}]$), it follows by Lemma 9 (resp. Lemma 10) that $v \in N[u_{i,1}] \setminus \{u_i, u_{i,2}\} \subseteq N[u_i]$ (resp. $v \in N[u_{i,3}] \setminus \{u_i, u_{i,4}\} \subseteq N[u_i]$), i.e. that $v$ is adjacent to $u_i$ in $G^*$, which is a contradiction. Thus, $\{u_{i,2}\}$ (resp. $\{u_{i,4}\}$) is a connected component of $G^* \setminus N[u_i]$.

Now suppose that $\{u_{i,2}\}$ (resp. $\{u_{i,4}\}$) is not a master component of $u_i$ in $G^*$. Then, there exists a connected component $V_0 \neq \{u_{i,2}\}$ (resp. $V_0 \neq \{u_{i,4}\}$) of $G^* \setminus N[u_i]$, such that $N(\{u_{i,2}\}) \subseteq N(V_0)$ (resp. $N(\{u_{i,4}\}) \subseteq N(V_0)$). Therefore, $u_{i,1} \in N(V_0)$ (resp. $u_{i,3} \in N(V_0)$), i.e. there exists a vertex $v \in V_0$, such that $v \in N[u_{i,1}]$ (resp. $v \in N[u_{i,3}]$). Thus, since $v \notin u_{i,2}$ (resp. $v \notin u_{i,4}$), Lemma 9 (resp. Lemma 10) implies that $v \in N[u_i]$, i.e. $V_0$ is not a connected component of $G^* \setminus N[u_i]$, which is a contradiction. Thus, $\{u_{i,2}\}$ (resp. $\{u_{i,4}\}$) is a master component of $u_i$ in $G^*$. Furthermore, since $u_{i,1} \in N(\{u_{i,2}\}) \setminus N(\{u_{i,4}\})$ and $u_{i,3} \in N(\{u_{i,4}\}) \setminus N(\{u_{i,2}\})$, it follows that $\{u_{i,4}\} \notin D_{u_i}^*(\{u_{i,2}\}) \neq \emptyset$ and that $\{u_{i,2}\} \notin D_{u_i}^*(\{u_{i,4}\}) \neq \emptyset$ in $G^*$. This completes the lemma. ■

4 The splitting of a trapezoid graph

In this section we present Algorithm Split-All, which takes as input the augmented graph $G^*$ with $5n$ vertices computed by the Algorithm Augment-All from the input graph $G$, and computes the graph $G^#$ with $6n$ vertices. This algorithm replaces every vertex of the input graph $G$ by a pair of new vertices in $G^#$. If the input graph $G$ is trapezoid, then $G^#$ is a permutation graph with a special structural property.
4.1 A splitting algorithm

In the following definition we state the notion of splitting a vertex in the augmented graph $G^\ast$ constructed by Algorithm Augment-All. The intuition behind this definition is the following. If $G$ is a trapezoid graph with $n$ vertices, then $G^\ast$ is a trapezoid graph with $5n$ vertices. Given a standard trapezoid representation $R^\ast$ of $G^\ast$ with respect to a vertex $u_i \in V(G) \subset V(G^\ast)$, we replace the trapezoid $T_{u_i}$ by the two trivial trapezoids in $R^\ast$, i.e., lines, $l(T_{u_i})$ and $r(T_{u_i})$. The two new vertices corresponding to the lines $l(T_{u_i})$ and $r(T_{u_i})$ are denoted by $u_{i,5}$ and $u_{i,6}$, respectively.

**Definition 5** Let: $G$ be a graph; $G^\ast$ be the augmented graph constructed by Algorithm Augment-All from $G$; $u_i \in V(G) \subset V(G^\ast)$; and the sets $N_X(u_i)$ be defined by Definition 1 with respect to the master component $\{u_{i,2}\}$ of $u_i$ in $G^\ast$, where $X \in \{1, 2, 12\}$. The graph $G^\#(u_i)$ obtained by the vertex splitting of $u_i$ in $G^\ast$ is defined as follows:

1. $V(G^\#(u_i)) = V(G^\ast) \setminus \{u_i\} \cup \{u_{i,5}, u_{i,6}\}$,  
2. $E(G^\#(u_i)) = E(V(G^\ast) \setminus \{u_i\}) \cup \{u_{i,5}x : x \in N_1(u_i) \cup N_{12}(u_i)\} \cup \{u_{i,6}x : x \in N_2(u_i) \cup N_{12}(u_i)\}$.

The vertices $u_{i,5}$ and $u_{i,6}$ are the derivatives of $u_i$.

After performing the splitting of a vertex $u_i$ of $G$, obtaining the graph $G^\#(u_i)$, we can continue by splitting an arbitrary vertex $v_j$ of $V(G) \setminus \{u_i\}$ in $G^\#(u_i)$. (Note that to do this further splitting, $\{u_{j,2}\}$ must still be a master component in $G^\#(u_i)$; this is proved in Lemma 15.) This process can be repeated $|V(G)|$ times, such that finally all vertices of $V(G)$ have been split, as presented in Algorithm Split-All. Note that, similarly to Algorithm Augment-All, also in this algorithm we choose an arbitrary ordering by which we split the vertices of $V(G)$. However, given the graph $G^\ast$ as input, the graph $G^\#$ computed by Algorithm Split-All is the same for any of these orderings. Intuitively, in a trapezoid representation of the augmented graph $G^\ast$, every trapezoid $T_{u_i}$ is replaced by its two lines $\ell(u_{i,5})$ and $\ell(u_{i,6})$, which intersect in the resulting trapezoid representation exactly with the same trapezoids as the lines $\ell(u_{i,2})$ and $\ell(u_{i,4})$, respectively.

**Algorithm 2 Split-All**

**Input:** The graph $G^\ast$ constructed by Algorithm Augment-All from $G$, where $V(G) = \{u_1, u_2, \ldots, u_n\}$

**Output:** The graph $G^\#$ obtained by splitting every vertex of $V(G)$ in $G^\ast$; also, the initial values of the sets $\hat{N}_i$, $i = 1, 2, \ldots, n$, which will be used in Algorithm 3

1: $H_0 \leftarrow G^\ast$  
2: for $i = 1$ to $n$ do  
3: $H_i \leftarrow H_{i-1}^\#(u_i)$ \{$H_i$ is obtained by the vertex splitting of $u_i$ of $H_{i-1}$\}  
4: $\hat{N}_i \leftarrow N_0(u_i)$ in $H_{i-1}$ \{these sets will be used in Algorithm 3\}  
5: $G^\# \leftarrow H_n$  
6: return $G^\#, \{\hat{N}_i, 1 \leq i \leq n\}$

At every step of Algorithm Split-All, the vertex $u_i$ of the graph $H_{i-1}$ is replaced by its two derivatives $u_{i,5}, u_{i,6}$ in $H_i$ by Definition 5. Therefore, since the input graph $G^\ast$ has $5n$ vertices, the graph $G^\# = H_n$ returned by Algorithm Split-All has in total $6n$ vertices. At the $i$th step of the algorithm, each of the two new vertices $u_{i,5}, u_{i,6}$ of $H_i$ has at most $|N_{H_{i-1}}(u_i)|$ neighbors.
in $H_i$. Since at every step of Algorithm Split-All, one vertex is replaced by two new ones, the number of edges in the graph $G' = H_n$ returned by the algorithm is not greater than four times the number of edges in the input graph $G^*$. Thus, since the input graph $G^*$ has $O(m)$ edges, the resulting graph $G'$ also has in total $O(m)$ edges. Therefore, since by Lemma 4 the sets $N_0, N_1, N_2,$ and $N_{12}$ for a graph with $n$ vertices and $m$ edges can be computed in $O(n + m)$ time, the next lemma follows similarly to Lemma 8.

**Lemma 12** Algorithm Split-All runs in $O(n(n + m))$ time.

Similarly to Lemma 9, we obtain the following lemma.

**Lemma 13** Let $u_i$ be a vertex of a graph $G$, and let $H_k$ be the graph constructed at the $k$th step of Algorithm Split-All, where $0 \leq k \leq i - 1$, i.e. before the splitting of vertex $u_i$. Then

- $N_{H_k}[u_i,2] = N_{H_k}[u_i,1] \setminus \{u_i\}$
- $N_{H_k}[u_i,1] \setminus \{u_i\} \subseteq N_{H_k}[u_i]$.

**Proof.** The lemma will be proved by induction on $k$. For $k = 0$ the lemma clearly holds due to Lemma 9, and since $H_0 = G^* = G_n$. Suppose that $N_{H_k}[u_i,2] = N_{H_k}[u_i,1] \setminus \{u_i\}$ and $N_{H_{k-1}}[u_i,1] \setminus \{u_i\} \subseteq N_{H_{k-1}}[u_i]$, for some $1 \leq k \leq i - 1$, i.e. before the splitting of vertex $u_i$. Consider the construction of the splitted graph $H_k$ from $H_{k-1}$ at the $k$th step of Algorithm Split-All: $H_k$ has the new vertices $u_{k,5}, u_{k,6}$ instead of the vertex $u_k$ in $H_{k-1}$. Similarly to the proof of Lemma 9, let $V_j$ be a master component of $u_k$ in $H_{k-1}$, and let $N_X(u_k), X \in \{1, 2, 12\}$, be the sets defined in Definitions 1 and 2 corresponding to the master component $V_j$.

**Case 1.** $D_{u_i}^*(V_j) \neq \emptyset$ in $H_{k-1}$ (cf. Definition 1). Suppose that $u_{i,2}$ is adjacent in $H_k$ to $u_{k,5}$ (resp. $u_{k,6}$), i.e. that $u_{i,2} \in N_1(u_k) \cup N_{12}(u_k)$ (resp. $u_{i,2} \in N_2(u_k) \cup N_{12}(u_k)$) in $H_{k-1}$. Then, $u_{i,2}$ is adjacent in $H_{k-1}$ to $u_k$ and to at least one vertex $v$ that belongs to a connected component of $H_{k-1} \setminus N_{H_{k-1}}[u_k]$, i.e. $u_k, v \in N_{H_{k-1}}[u_{i,2}]$. It follows by the induction hypothesis that $u_k, v \in H_{k-1}[u_{i,1}]$, and thus, $u_{i,1} \in N_1(u_k) \cup N_{12}(u_k)$ (resp. $u_{i,1} \in N_2(u_k) \cup N_{12}(u_k)$) in $H_{k-1}$. Therefore, $u_{i,1}$ is adjacent in $H_k$ to $u_{k,5}$ (resp. $u_{k,6}$) as well. Thus, $N_{H_k}[u_{i,2}] \subseteq N_{H_k}[u_{i,1}] \setminus \{u_i\}$.

To prove the other direction of this set inclusion, we first suppose that $u_{i,1}$ is adjacent in $H_k$ to $u_{k,5}$ (resp. $u_{k,6}$), i.e. that $u_{i,1} \in N_1(u_k) \cup N_{12}(u_k)$ (resp. $u_{i,1} \in N_2(u_k) \cup N_{12}(u_k)$) in $H_{k-1}$. Then, similarly to the previous paragraph, $u_{i,1}$ is adjacent in $H_{k-1}$ to $u_k$ and to at least one vertex $v$ that belongs to a connected component of $H_{k-1} \setminus N_{H_{k-1}}[u_k]$, i.e. $u_k, v \in N_{H_{k-1}}[u_{i,1}]$. Since $N_{H_{k-1}}[u_{i,1}] \setminus \{u_{i,2}\} \subseteq N_{H_{k-1}}[u_{i,1}]$, and since $u_{i,2} \neq u_k$, it follows that $u_k \in H_{k-1}[u_{i,1}]$. Thus, $u_i \neq v$, i.e. $u_k, v \in N_{H_{k-1}}[u_{i,1}] \setminus \{u_i\}$. Therefore, it follows by the induction hypothesis that $u_k, v \in H_{k-1}[u_{i,1}]$, and thus, $u_{i,2} \in N_1(u_k) \cup N_{12}(u_k)$ (resp. $u_{i,2} \in N_2(u_k) \cup N_{12}(u_k)$) in $H_{k-1}$. Therefore, $u_{i,2}$ is adjacent in $H_k$ to $u_{k,5}$ (resp. $u_{k,6}$) as well. Thus, $N_{H_k}[u_{i,2}] \subseteq N_{H_k}[u_{i,1}] \setminus \{u_i\}$. Summarizing, $N_{H_k}[u_{i,2}] = N_{H_k}[u_{i,1}] \setminus \{u_i\}$ for the case where $D_{u_i}^*(V_j) \neq \emptyset$.

Furthermore, since $u_k, v \in N_{H_{k-1}}[u_{i,2}]$, it follows that $u_{i,2} \not\in \{u_k, v\}$. Thus $u_k, v \in N_{H_k}[u_{i,1}] \setminus \{u_{i,2}\}$, and thus $u_{i,1} \in N_1(u_k) \cup N_{12}(u_k)$ (resp. $u_{i,1} \in N_2(u_k) \cup N_{12}(u_k)$) in $H_{k-1}$. Therefore $u_{i,1}$ is adjacent in $H_k$ to $u_{k,5}$ (resp. $u_{k,6}$) as well, i.e. $N_{H_k}[u_{i,1}] \setminus \{u_{i,2}\} \subseteq N_{H_k}[u_{i,1}]$. This completes the induction step for the case where $D_{u_i}^*(V_j) \neq \emptyset$.

**Case 2.** $D_{u_k}^*(V_j) = \emptyset$ in $H_{k-1}$ (cf. Definition 2). Then, $N_2(u_k) = \emptyset$ in $H_{k-1}$. First suppose that $u_{i,2}$ is adjacent in $H_k$ to $u_{k,5}$, i.e. $u_{i,2} \in N_1(u_k) \cup N_{12}(u_k) = N_{H_{k-1}}[u_k] \setminus N_0(u_k)$ in $H_{k-1}$. Then, $u_{i,2}$ is adjacent in $H_{k-1}$ to $u_k$ and to at least one vertex $v$ that belongs to the master component $V_j$ of $u_k$. Thus, since $u_k, v \in N_{H_{k-1}}[u_{i,2}]$, it follows by the induction hypothesis that $u_k, v \in H_{k-1}[u_{i,1}]$, and thus $u_{i,1} \in N_{H_{k-1}}[u_k] \setminus N_0(u_k) = N_1(u_k) \cup N_{12}(u_k)$ in $H_{k-1}$. Hence $u_i$ is adjacent in $H_k$ to $u_{k,5}$ as well.
Now suppose that \( u_{i,2} \) is adjacent in \( H_k \) to \( u_{k,6} \), i.e. \( u_{i,2} \in N_{12}(u_k) \subseteq N_{H_k-1}(u_k) \setminus N_0(u_k) \) in \( H_{k-1} \). Similarly to the previous paragraph, \( u_{i,1} \in N_{H_k-1}(u_k) \setminus N_0(u_k) = N_1(u_k) \cup N_{12}(u_k) \) in \( H_{k-1} \) as well. Furthermore, since \( u_{i,2} \in N_{12}(u_k) \), it follows by Definition 2 and by the induction hypothesis that \( N_0(u_k) \subseteq N_{H_k-1}(u_{i,2}) \subseteq N_{H_k-1}[u_{i,1}] \). Since \( u_{i,1} \notin N_0(u_k) \), \( N_0(u_k) \subseteq N_{H_k-1}(u_{i,1}) \), and therefore, \( u_{i,1} \) is adjacent in \( H_k \) to \( u_{k,6} \) as well. Summarizing, \( N_{H_k[u_{i,2}]} \subseteq N_{H_k[u_{i,1}]} \setminus \{u_i\} \).

Suppose that \( u_{i,1} \) is adjacent in \( H_k \) to \( u_{k,5} \), i.e. that \( u_{i,1} \in N_1(u_k) \cup N_{12}(u_k) \) in \( H_{k-1} \). Then \( u_{i,1} \) is adjacent in \( H_{k-1} \) to \( u_k \) and to at least one vertex \( v \) that belongs to the master component \( V_j \) of \( u_k \), i.e. \( u_k \in N_{H_k-1}(u_{i,1}) \). Since \( N_{H_k-1}[u_{i,1}] \setminus \{u_{i,2}\} \subseteq N_{H_k-1}[u_1] \), and since \( u_{i,2} \neq u_k \), it follows that \( u_k \in N_{H_k-1}[u_{i,1}] \). Thus \( u_i \notin v \), i.e. \( u_k \in N_{H_k-1}[u_{i,1}] \setminus \{u_i\} = N_{H_k-1}[u_{i,2}] \) by the induction hypothesis. It follows that \( u_{i,2} \in N_{H_k-1}(u_k) \setminus N_0(u_k) = N_1(u_k) \cup N_{12}(u_k) \) in \( H_{k-1} \). Hence \( u_{i,2} \) is adjacent in \( H_k \) to \( u_{k,5} \) as well. Furthermore, since \( u_k \in N_{H_k-1}[u_{i,2}] \), it follows that \( u_{i,2} \notin \{u_k, v\} \). Thus \( u_k, v \in N_{H_k}[u_{i,1}] \setminus \{u_{i,2}\} \subseteq N_{H_k}[u_i] \), and thus, \( u_i \in N_{H_k-1}(u_k) \setminus N_0(u_k) = N_1(u_k) \cup N_{12}(u_k) \) in \( H_{k-1} \). Hence \( u_i \) is adjacent in \( H_k \) to \( u_{k,5} \) as well.

Now suppose that \( u_{i,1} \) is adjacent in \( H_k \) to \( u_{k,6} \), i.e. that \( u_{i,1} \in N_1(u_k) \cup N_{12}(u_k) \) in \( H_{k-1} \). Similarly to the previous paragraph, \( u_{i,2}, u_i \in N_{H_k-1}(u_k) \setminus N_0(u_k) = N_1(u_k) \cup N_{12}(u_k) \) in \( H_{k-1} \) as well. Furthermore it follows by Definition 2 that \( N_0(u_k) \subseteq N_{H_k-1}(u_{i,1}) \). By the induction hypothesis, and since \( u_{i,2} \notin N_0(u_k) \), we see that \( N_0(u_k) \subseteq N_{H_k-1}[u_{i,1}] \setminus \{u_i\} = N_{H_k-1}[u_{i,2}] \) and \( N_0(u_k) \subseteq N_{H_k-1}[u_{i,1}] \setminus \{u_{i,2}\} \subseteq N_{H_k-1}[u_{i,1}] \). That is, \( N_0(u_k) \subseteq N_{H_k-1}[u_{i,2}] \) and \( N_0(u_k) \subseteq N_{H_k-1}[u_{i,1}] \), since \( u_{i,2} \), \( u_i \notin N_0(u_k) \). Therefore \( u_{i,1} \), \( u_i \in N_{12}(u_k) \) in \( H_{k-1} \), i.e. \( u_{i,2} \) and \( u_i \) are adjacent in \( H_k \) to \( u_{k,6} \) as well. Summarizing, \( N_{H_k[u_{i,2}]} = N_{H_k}[u_{i,1}] \setminus \{u_{i}\} \) and \( N_{H_k[u_{i,1}]} \setminus \{u_{i,2}\} \subseteq N_{H_k}[u_i] \). This proves the induction step in the case where \( D_{u_k}^*(V_j) = \emptyset \).

The following lemma is symmetric to Lemma 13.

**Lemma 14** Let \( u_i \) be a vertex of a graph \( G \), and let \( H_k \) be the graph constructed at the \( k \)th step of Algorithm Split-All, where \( 0 \leq k \leq i - 1 \), i.e. before the splitting of vertex \( u_i \). Then

- \( N_{H_k[u_{i,2}]} = N_{H_k[u_{i,1}]} \setminus \{u_i\} \)
- \( N_{H_k[u_{i,3}]} \setminus \{u_{i,2}\} \subseteq N_{H_k}[u_i] \).

Recall by Definition 5 that the notion of splitting a vertex \( u_i \) is well defined if there exists a master component \( \{u_{i,2}\} \) of \( u_i \) (with one vertex), such that \( D_{u_i}^*(\{u_{i,2}\}) \neq \emptyset \) (cf. Definition 1). In the next lemma (which extends Lemma 11) we prove that the notion of vertex splitting is well defined at every step of Algorithm Split-All, i.e. that Algorithm Split-All is well defined.

**Lemma 15** Let \( u_i \) be a vertex of a graph \( G \), and let \( H_k \) be the graph constructed at the \( k \)th step of Algorithm Split-All, where \( 0 \leq k \leq i - 1 \), i.e. before the splitting of vertex \( u_i \). Then \( \{u_{i,2}\} \) and \( \{u_{i,4}\} \) are master components of \( u_i \) in \( H_k \). Furthermore \( D_{u_i}^*(\{u_{i,2}\}) \neq \emptyset \) and \( D_{u_i}^*(\{u_{i,4}\}) \neq \emptyset \) in \( H_k \).

**Proof.** For \( k = 0 \) the lemma holds clearly due to Lemma 11, and since \( H_0 = G^* \). Now consider the graph \( H_k \) constructed at the \( k \)th step of Algorithm Split-All, where \( 1 \leq k \leq i - 1 \), i.e. before the splitting of vertex \( u_i \). For simplicity reasons, in the proof we will denote the neighborhood \( N_{H_k}(U) \) of a vertex set \( U \) in \( H_k \) by \( N(U) \). First suppose that \( \{u_{i,2}\} \) (resp. \( \{u_{i,4}\} \)) is not a connected component of \( H_k \setminus N[u_i] \). Then, since \( u_{i,2} \) (resp. \( u_{i,4} \)) is not adjacent to \( u_i \) in \( H_k \), there must be at least one vertex \( v \) of \( H_k \), which is adjacent to \( u_{i,2} \) (resp. \( u_{i,4} \)) and not to \( u_i \) in \( H_k \). However, since \( v \notin \{u_{i,2}, u_{i,4}\} \), and since \( v \notin N[u_{i,2}] \) (resp. \( v \notin N[u_{i,4}] \)), it follows by Lemma 13 (resp. Lemma 14) that \( v \in N[u_{i,1}] \setminus \{u_{i,2}\} \subseteq N[u_i] \) (resp. \( v \in N[u_{i,3}] \setminus \{u_{i,4}\} \subseteq N[u_i] \)), i.e. that \( v \) is adjacent to \( u_i \) in \( H_k \), which is a contradiction. Thus \( \{u_{i,2}\} \) (resp. \( \{u_{i,4}\} \)) is a connected component of \( H_k \setminus N[u_i] \).
Now suppose that \( \{u_{i,2}\} \) (resp. \( \{u_{i,4}\} \)) is not a master component of \( u_i \) in \( H_k \). Then there exists a connected component \( V_0 \neq \{u_{i,2}\} \) (resp. \( V_0 \neq \{u_{i,4}\} \)) of \( H_k \backslash N[u_i] \), such that \( N(\{u_{i,2}\}) \subset N(V_0) \) (resp. \( N(\{u_{i,4}\}) \subset N(V_0) \)). Therefore \( u_{i,1} \in N(V_0) \) (resp. \( u_{i,3} \in N(V_0) \)), i.e. there exists a vertex \( v \in V_0 \), such that \( v \in N[u_{i,1}] \) (resp. \( v \in N[u_{i,3}] \)). Thus, since \( v \neq u_{i,2} \) (resp. \( v \neq u_{i,4} \)), Lemma 13 (resp. Lemma 14) implies that \( v \in N[u_i] \), i.e. \( V_0 \) is not a connected component of \( H_k \backslash N[u_i] \), which is a contradiction. Thus \( \{u_{i,2}\} \) (resp. \( \{u_{i,4}\} \)) is a master component of \( u_i \) in \( H_k \). Furthermore, since \( u_{i,1} \in N(\{u_{i,2}\}) \backslash N(\{u_{i,4}\}) \) and \( u_{i,3} \in N(\{u_{i,4}\}) \backslash N(\{u_{i,2}\}) \), it follows that \( \{u_{i,4}\} \in \hat{D}_{u_i}(\{u_{i,2}\}) \neq \emptyset \) and that \( \{u_{i,2}\} \in \hat{D}_{u_i}^*(\{u_{i,4}\}) \neq \emptyset \) in \( H_k \). This completes the lemma. □

Since we split every vertex of \( G \) exactly once in \( G^* \), and since \( G^* \) has \( 5n \) vertices, where \( |V(G)| = n \), the graph \( G^\# \) computed by Algorithm Split-All has \( 6n \) vertices. Furthermore, if the input graph \( G \) is trapezoid, then \( G^\# \) is a permutation graph, cf. Theorem 1.

Indeed, in this case \( G^* \) is also a trapezoid graph, where the trapezoids corresponding to the augmenting vertices, i.e. the vertices of \( V(G^*) \setminus V(G) \), are trivial (lines), and at every iteration a trapezoid \( T_u \) is replaced by the two trivial trapezoids (lines) \( l(T_u) \) and \( r(T_u) \). Denote by \( R^\# \) the resulting permutation representation of \( G^\# \). In the following, we will specify which of the \( 6n \) lines in \( R^\# \) lie between the lines corresponding to the vertex derivatives \( u_{i,5}, u_{i,6} \) of a vertex \( u_i \) of \( G \).

4.2 The computation of the intermediate lines

In this section, we present Algorithm Intermediate-Lines that updates the sets \( \{\tilde{N}_i\} \) initialized in Algorithm Split-All (Algorithm 2). If \( G \) is a trapezoid graph (and thus \( G^\# \) is a permutation graph), then as shown in Lemma 17, for each \( i = 1, \ldots, n \), \( \tilde{N}_i \) contains the vertices of \( G^\# \) whose corresponding lines lie between \( u_{i,5} \) and \( u_{i,6} \) in \( R^\# \). For simplicity reasons, we may identify in the sequel the vertices of \( G^\# \) with the corresponding lines in \( R^\# \).

**Algorithm 3 Intermediate-Lines**

**Input:** The splitted graph \( G^\# \), and for each \( i = 1, \ldots, n \) the set \( \tilde{N}_i \) computed in Algorithm Split-All.

**Output:** The updated set \( \tilde{N}_i \), for each \( i = 1, \ldots, n \). If \( G \) is trapezoid, then \( \{\tilde{N}_i\} \) satisfies Lemma 17.

1: for \( i = 1 \) to \( n - 1 \) do
2: for \( j = i + 1 \) to \( n \) do
3: if \( u_{j,2} \in \tilde{N}_i \) then
4: \( \tilde{N}_i \leftarrow (\tilde{N}_i \setminus \{u_j\}) \cup \{u_{j,5}\} \)
5: if \( u_{j,4} \in \tilde{N}_i \) then
6: \( \tilde{N}_i \leftarrow (\tilde{N}_i \setminus \{u_j\}) \cup \{u_{j,6}\} \)
7: return \( \tilde{N}_i \), for every \( i = 1, 2, \ldots, n \)

Since Algorithm Intermediate-Lines iterates for every pair \((i, j), ~1 \leq i < j \leq n\), and since (by using the 0-1 membership vectors used in the proof of Lemma 4) every iteration can be computed in constant time, the next lemma follows easily.

**Lemma 16** Algorithm Intermediate-Lines runs in \( O(n^2) \) time.

**Lemma 17** Let \( G \) be a trapezoid graph on \( n \) vertices, let \( G^\# \) be the graph computed by Algorithm Split-All, and let \( R^\# \) be a representation of \( G^\# \). For every \( i = 1, 2, \ldots, n \), the lines that lie
between the derivatives $u_{i,5}$ and $u_{i,6}$ in $R^\#$ correspond to the vertices of the set $\tilde{N}_i$ computed by Algorithm Intermediate-Lines.

**Proof.** Let $G$ be a trapezoid graph and let $G^*$ be the trapezoid graph constructed by Algorithm Augment-All (Algorithm 1). Let $H_i$, $i = 1, 2, \ldots, n$ be the trapezoid graph constructed at the $i$th iteration of Algorithm Split-All (Algorithm 2), (i.e. vertex $u_i$ has just been split) where $H_0 = G^*$. For the purposes of the proof, denote by $\overline{R}_{i-1}$, $i = 1, 2, \ldots, n$, a standard trapezoid representation of $H_{i-1}$ with respect to $u_i$ (before the splitting of vertex $u_i$). Furthermore, denote by $R_i$, $i = 1, 2, \ldots, n$, the trapezoid representation of $H_i$, which is obtained from $\overline{R}_{i-1}$, when we replace the trapezoid $T_u$ by the lines $l(T_u)$ and $r(T_u)$ (during the splitting of vertex $u_i$). Recall that these lines correspond to the derivatives $u_{i,5}$ and $u_{i,6}$ of $u_i$ of $H_i$. Algorithm Intermediate-Lines iterates for every $i = 1, 2, \ldots, n$ and for every $j = i + 1, i + 2, \ldots, n$. We let $\tilde{N}_{i,j}$ denote the value of $\tilde{N}_i$ at the end of the $j$th iteration. We will prove by induction on $j$ that, after the iteration that corresponds to a pair $(i, j)$, $\tilde{N}_{i,j}$ is exactly the set of vertices of $H_j$, whose trapezoids lie between $u_{i,5}$ and $u_{i,6}$ in $R_j$. Due to Lemma 5, it is easy to see that initially, i.e. for $j = i$, $\tilde{N}_{i,i} = N_0(u_i)$ is the set of vertices of $H_i$, whose trapezoids lie between the derivatives $u_{i,5}$ and $u_{i,6}$ of $u_i$ in $R_i$ (in particular, $\tilde{N}_{n-1,n}$ is the set of lines that lie between $u_{n,5}$ and $u_{n,6}$ in $R_n = R^\#$). This proves the induction basis.

Now suppose that $\tilde{N}_{i,j-1}$ is exactly the set of vertices of $H_{j-1}$, whose trapezoids lie between the derivatives $u_{i,5}$ and $u_{i,6}$ in $R_{j-1}$, for some index $j$, where $i + 1 \leq j \leq n$. Consider the standard trapezoid representation $\overline{R}_{j-1}$ of $H_{j-1}$ with respect to $u_j$, which is constructed by the proof of Lemma 5 from $R_{j-1}$. By Definition 5, let $N_1(u_j)$, $N_2(u_j)$, and $N_{12}(u_j)$ be the sets defined by Definition 1 with respect to the master component $\{u_j,2\}$ of $u_j$ in $H_{j-1}$. Namely $N_1(u_j) \cup N_{12}(u_j)$ are those neighbors of $u_j$ in $H_{j-1}$ which are also adjacent to $u_{j,2}$, while $N_2(u_j) \cup N_{12}(u_j)$ are those neighbors of $u_j$ in $H_{j-1}$, which are also adjacent to $D^u_*(\{u_j,2\})$. Due to Lemma 15, $\{u_{j,4}\}$ is also a master component of $u_j$ in $H_{j-1}$, while $\{u_{j,4}\} \in D^u_*(\{u_j,2\})$. Thus, Lemma 3 implies that $N_2(u_j) \cup N_{12}(u_j)$ includes those neighbors of $u_j$ in $H_{j-1}$ which are also adjacent to $u_{j,4}$.

Since $\overline{R}_{j-1}$ is a standard trapezoid representation of $H_{j-1}$ with respect to $u_j$, it follows by Definition 3 that the line $l(T_{u_j})$, which corresponds to the vertex $u_{j,5}$ (resp. the line $r(T_{u_j})$, which corresponds to the vertex $u_{j,6}$) intersects exactly with the trapezoids of $N_1(u_j) \cup N_{12}(u_j)$ (resp. $N_2(u_j) \cup N_{12}(u_j)$) in $\overline{R}_{j-1}$. Thus, after replacing in $\overline{R}_{j-1}$ the trapezoid $T_{u_j}$ by its lines $l(T_{u_j})$ and $r(T_{u_j})$, the lines $u_{j,5}$ and $u_{j,2}$ (resp. $u_{j,6}$ and $u_{j,4}$) of $H_j$ intersect with the same trapezoids in $R_j$, namely with the trapezoids of $N_1(u_j) \cup N_{12}(u_j)$ (resp. $N_2(u_j) \cup N_{12}(u_j)$). Furthermore, since $u_{j,5}$ intersects $u_{j,1}$ (resp. $u_{j,6}$ intersects $u_{j,3}$), and since $u_{j,1}$ intersects $u_{j,2}$ (resp. $u_{j,3}$ intersects $u_{j,4}$) in $H_j$, it is easy to see that $u_{j,5}$ (resp. $u_{j,6}$) lies between $u_{i,5}$ and $u_{i,6}$ in $R_j$ if and only if $u_{j,2}$ (resp. $u_{j,4}$) lies between $u_{i,5}$ and $u_{i,6}$ in $R_j$ as well. Thus, after the iteration that corresponds to a pair $(i, j)$, $\tilde{N}_{i,j}$ is exactly the set of vertices of $H_j$, whose trapezoids lie between $u_{i,5}$ and $u_{i,6}$ in $R_j$. This completes the induction step, and thus, the lemma follows.

**Theorem 1** A graph $G$ on $n$ vertices is a trapezoid graph if and only if the graph $G^\#$ with $6n$ vertices constructed by Algorithm Split-All is a permutation graph, with a permutation representation $R^\#$, such that $\tilde{N}_i$ is exactly the set of vertices of $G^\#$, whose lines lie between the vertex derivatives $u_{i,5}$ and $u_{i,6}$ in $R^\#$, for every $i = 1, 2, \ldots, n$.

**Proof.** The necessity part of the proof follows by Lemma 17. For the sufficiency part, consider a permutation representation $R^\#$ of $G^\#$, such that $\tilde{N}_i$ is exactly the set of vertices of $G^\#$, whose lines lie between the vertex derivatives $u_{i,5}$ and $u_{i,6}$ in $R^\#$, for every $i = 1, 2, \ldots, n$. Let
$R_n = R^\#$. We construct a trapezoid representation $R_0$ as follows. For every $i = n, n - 1, \ldots, 1$, we replace in $R_i$ the lines of the vertices $v_{i,5}$ and $v_{i,6}$ by a trapezoid $T_{u_i}$ defined by these lines, obtaining the trapezoid representation $R_{i-1}$. We will prove by induction on $i$ that $R_i$ is a trapezoid representation of $H_i$ (the graph constructed at the $i$th step of Algorithm Split-All), for every $i = n, n - 1, \ldots, 1, 0$, from which it then follows that $R_0$ is a trapezoid representation of $H_0$. For $i = n$, $R_n = R^\#$ is clearly a trapezoid representation of $G^\# = H_n$, since $R^\#$ is by assumption a permutation representation of $G^\#$. This proves the induction basis.

For the induction step, suppose that $R_i$ is a trapezoid representation of $H_i$, for some $i$, where $1 \leq i \leq n$. All vertices of $H_i$ other than $v_{i,5}$ and $v_{i,6}$ are either $u_{j,k}$ for some $j \in \{1, 2, \ldots, n\}$ and $k \in \{1, 2, 3, 4\}$ (i.e. augmenting vertices), or $u_{j,k}$ for some $j \in \{1, 2, \ldots, i-1\}$ and $k \in \{5, 6\}$ (i.e. other vertex derivatives), or $u_j$ for some $j \in \{i+1, \ldots, n\}$ (i.e. vertices of $G$, which are unsplitted in $H_i$, and thus are represented by trapezoids in $R_i$). Consider now an arbitrary vertex $v \notin \{v_{i,5}, v_{i,6}\}$ of $H_i$. We will distinguish in the following three cases regarding the vertex $v$.

Case 1. Suppose that $v \in N_1(u_i) \cup N_2(u_i) \cup N_{12}(u_i)$ in $H_{i-1}$, i.e. $T_v$ intersects by Definition 5 at least one of the derivatives $v_{i,5}$ and $v_{i,6}$ in $R_i$. Then, in particular $v \in N_{H_{i-1}}(u_i)$, and thus $T_v$ correctly intersects the new trapezoid $T_{u_i}$ of the trapezoid representation $R_{i-1}$.

Case 2. Suppose that $v \notin N_1(u_i) \cup N_2(u_i) \cup N_{12}(u_i)$ in $H_{i-1}$, where $v$ is either an augmenting vertex or a derivative of a vertex $u_j$ for some $j \leq i - 1$. Then, by the initialization of the set $\hat{N}_i$ in line 4 of Algorithm Split-All, $v \in \hat{N}_i$ if and only if $v \in N_{0}(u_i)$ in $H_{i-1}$, since $v$ is neither added to nor removed from $\hat{N}_i$ by Algorithm Intermediate-Lines. Thus, by our assumption on the initial permutation representation $R^\#$, the line $T_v$ lies between the derivatives $u_{i,5}$ and $u_{i,6}$ in $R_i$ if and only if $v \in N_{0}(u_i)$ in $H_{i-1}$, or equivalently, if and only if $v \in N_{H_{i-1}}(u_i)$ (since by assumption $v \notin N_1(u_i) \cup N_2(u_i) \cup N_{12}(u_i)$ in $H_{i-1}$). Thus, for every such vertex $v$ of $H_{i-1}$, $T_v$ intersects the new trapezoid $T_{u_i}$ of the trapezoid representation $R_{i-1}$ if and only if $v \in N_{H_{i-1}}(u_i)$.

Case 3. Suppose that $v \notin N_1(u_i) \cup N_2(u_i) \cup N_{12}(u_i)$ in $H_{i-1}$, where $v = u_j$ for some $j \geq i+1$, i.e. $v$ is an unsplitted vertex of $H_i$. In this case, $T_{u_j}$ does not intersect the derivatives $u_{i,5}$ and $u_{i,6}$ in $R_i$, and thus $T_{u_j}$ either lies to the right or to the left of both $u_{i,5}$ and $u_{i,6}$ in $R_i$, or lies between $u_{i,5}$ and $u_{i,6}$ in $R_i$.

Case 3a. First suppose that $T_{u_j}$ lies to the right or to the left of both $u_{i,5}$ and $u_{i,6}$ in $R_i$. Then, in particular, it is easy to see that at least one of the lines of the augmenting vertices $u_{j,1}$ and $u_{j,3}$ lies to the right or to the left of both $u_{i,5}$ and $u_{i,6}$ in $R_i$. We will prove that in this case $u_j \notin N_{H_{i-1}}(u_i)$. Suppose otherwise that $u_j \in N_{H_{i-1}}(u_i)$. Then, since by assumption $u_j \notin N_1(u_i) \cup N_2(u_i) \cup N_{12}(u_i)$ in $H_{i-1}$, it follows that $u_j \in N_{0}(u_i)$ in $H_{i-1}$, i.e. every neighbor of $u_j$ in $H_{i-1}$ is also a neighbor of $u_i$ in $H_{i-1}$. Therefore, in particular, both $u_{j,1}$ and $u_{j,3}$ are neighbors of $u_i$ in $H_{i-1}$. Thus, each $w \in \{u_{j,1}, u_{j,3}\}$ either lies between the derivatives $u_{i,5}$ and $u_{i,6}$ in $R_i$ (in the case where $w \in N_0(u_i)$ in $H_{i-1}$, or equivalently $w \in \hat{N}_i$), or intersects at least one of the derivatives $u_{i,5}$ and $u_{i,6}$ in $R_i$ (in the case where $w \in N_1(u_i) \cup N_2(u_i) \cup N_{12}(u_i)$ in $H_{i-1}$). This is a contradiction, since at least one of the lines of the augmenting vertices $u_{j,1}$ and $u_{j,3}$ lies to the right or to the left of both $u_{i,5}$ and $u_{i,6}$ in $R_i$, as we proved above. Therefore, $u_j \notin N_{H_{i-1}}(u_i)$ in the case where $T_{u_j}$ lies to the right or to the left of both $u_{i,5}$ and $u_{i,6}$ in $R_i$, and thus $T_{u_j}$ correctly does not intersect the new trapezoid $T_{u_i}$ of the trapezoid representation $R_{i-1}$.

Case 3b. Now suppose that $T_{u_j}$ lies between $u_{i,5}$ and $u_{i,6}$ in $R_i$. Then, both $u_{i,5}$ and $u_{i,6}$ lie between $u_{i,5}$ and $u_{i,6}$ in the initial permutation representation $R^\#$, and thus $u_{j,5}, u_{j,6} \in \hat{N}_i$ by our assumption on $R^\#$. Therefore, in particular, $u_{j,2} \in \hat{N}_i$ by Algorithm Intermediate-Lines, and thus also $u_{j,2} \in N_0(u_i)$ in $H_{i-1}$ by the initialization of the set $\hat{N}_i$ in line 4 of Algorithm Split-All. That is, $u_{j,2} \in N_{H_{i-1}}(u_i)$, or equivalently $u_i \in N_{H_{i-1}}(u_{j,2})$. Therefore, since $0 \leq i - 1 < j - 1$, it
follows by Lemma 13 that $u_i \in N_{H_{i-1}}(u_{j,1})$ and $u_i \in N_{H_{i-1}}(u_j)$. Thus $T_{u_j}$ correctly intersects the new trapezoid $T_{u_i}$ of the trapezoid representation $R_{i-1}$.

Summarizing, in the trapezoid representation $R_{i-1}$, the new trapezoid $T_{u_i}$ intersects exactly with the trapezoids $T_v$, such that $v \in N_{H_{i-1}}(u_i)$, and thus $R_{i-1}$ is a trapezoid representation of $H_{i-1}$. This completes the induction step. Therefore $R_0$ is a trapezoid representation of $H_0 = G^*$, i.e. $G^*$ is a trapezoid graph, and thus $G$ is a trapezoid graph as well by Corollary 1. Then a trapezoid representation $R$ of $G$ can be obtained by removing from $R_0$ the lines of the vertices $u_{i,1}, u_{i,2}, u_{i,3}, u_{i,4}$ for every $i = 1, 2, \ldots, n$. This completes the lemma. ■

5 T-orientations of graphs

Our trapezoid recognition algorithm interprets the property of permutation graphs stated in Theorem 1 in terms of transitive orientations. In this section we extend the notion of a transitive orientation of a graph to the notion of a $T$-orientation, and in Section 6, we provide an algorithm for computing a $T$-orientation, if one exists. Recall that a graph is transitively orientable if and only if it is a comparability graph [6]. For simplicity of the presentation, in this section $G$ denotes an arbitrary graph, and not the input graph discussed in Sections 2, 3, and 4. We first give some definitions on arbitrary graphs that will be used in the sequel.

Definition 6 Given an edge $e = xy$ of a graph $G = (V, E)$, $\tilde{N}(xy) = \{v \in V : vx, vy \in E\}$ is the set of vertices adjacent to both $x$ and $y$ in $E$, and $\tilde{E}(xy) = \{uv \in E : u \in \tilde{N}(xy), v \in \{x, y\}\} \cup \{xy\}$ is the set of edges with one endpoint in $\tilde{N}(xy)$ and the other in $\{x, y\}$, as well as the edge $xy$.

Definition 7 Let $G = (V, E)$ be a graph. An edge neighborhood set $N = \{e, N'\}$ consists of an edge $e = xy \in E$ of $G$, together with a vertex subset $N' \subseteq \tilde{N}(xy)$.

Definition 8 Let $F$ be a transitive orientation of $G = (V, E)$, and let $e = xy \in E$ be an edge of $G$. The $T$-interval $I_F(e)$ of $e$ is the vertex set defined as follows:

1. if $\langle xy \rangle \in F$, then $I_F(e) = \{z \in V : \langle xz \rangle, \langle zy \rangle \in F\}$,

2. if $\langle yx \rangle \in F$, then $I_F(e) = \{z \in V : \langle yz \rangle, \langle zx \rangle \in F\}$.

The $T$-interval $I_F(e)$ of an edge $e = xy$ includes exactly the vertices $z$ of $G$, whose incident arcs to $x$ and $y$ in $F$ imply the arc $\langle xy \rangle$ (or $\langle yx \rangle$) in $F$ by direct transitivity. Note that, by Definition 6, for the $T$-interval $I_F(e)$ of an edge $e = xy$, $I_F(e) \subseteq \tilde{N}(xy)$.

Definition 9 Let $N_i = \{e_i, N'_i\}, i = 1, 2, \ldots, k$, be a set of edge neighborhood sets in $G$. If there exists a transitive orientation $F$ of $G$ such that $I_F(e) = N'_i$ for every $i = 1, 2, \ldots, k$, then $F$ is called a $T$-orientation on $N_1, N_2, \ldots, N_k$, and $G$ is called $T$-orientable on these edge neighborhood sets.

In the following we define the notion of deactivating an edge $e_k$ of $G$, where $N_k = \{e_k, N'_k\}$ is an edge neighborhood set in $G$. The constructed graph $\tilde{G}(e_k)$ has four new vertices and will be used for our trapezoid recognition algorithm.

Definition 10 Let $G$ be a graph and let $N_i = \{e_i, N'_i\}$ be an edge neighborhood set in $G$, where $e_i = x_iy_i$. The graph $\tilde{G}(e_i)$ obtained by deactivating the edge $e_i$ is defined as follows:

1. $V(\tilde{G}(e_i)) = V(G) \cup \{a_i, b_i, c_i, d_i\}$,
2. \( E(\tilde{G}(e_i)) = E(G) \cup \{x_ia_i, a_ib_i, b_ic_i, c_id_i, d_iz_i \} \cup \{a_iz, b_iz, c_iz, d_iz : z \in \tilde{N}(x_iy_i) \setminus N'_i \} \).

An example of the deactivation operation can be seen in Figure 5. In this example, \( z_1 \in N'_i, z_2 \in \tilde{N}(x_iy_i) \setminus N'_i \), \( w_1 \in N(x_i) \setminus N(y_i) \), and \( w_2 \in N(y_i) \setminus N(x_i) \). For better visibility, the edges of \( \tilde{G}(e_i) \setminus E(G) \) are drawn with dashed lines.

![Figure 5](image)

Figure 5: (a) A graph \( G \) and (b) the graph \( \tilde{G}(e_i) \) obtained after the deactivation of \( e_i = x_iy_i \) with respect to \( N_i = \{e_i, \{z_1\} \} \).

**Lemma 18** Let \( G \) be a graph and let \( N_i = \{e_i, N'_i\}, i = 1, 2, \ldots, k \), be a set of edge neighborhood sets in \( G \). Then, \( G \) is T-orientable on \( N_1, N_2, \ldots, N_k \) if and only if \( \tilde{G}(e_k) \) is T-orientable on \( N_1, N_2, \ldots, N_{k-1} \).

**Proof.** Let \( e_k = x_ky_k \). Suppose first that the graph \( G = (V, E) \) is T-orientable on \( N_1, N_2, \ldots, N_k \), and let \( F \) be a T-orientation of \( G \) on these neighborhood sets. Without loss of generality we may assume that \( \langle x_ky_k \rangle \in F \). We will extend \( F \) to an orientation \( F' \) of \( \tilde{G}(e_k) \), as follows. First, orient the arcs \( \langle x_ka_k \rangle, \langle b_ka_k \rangle, \langle b_kc_k \rangle, \langle d_kc_k \rangle \) and \( \langle d_ky_k \rangle \) in \( F' \). For every \( z \in \tilde{N}(x_ky_k) \setminus N'_k \), either \( \langle zx_k \rangle, \langle zy_k \rangle \in F \) or \( \langle x_kz \rangle, \langle y_kz \rangle \in F \). If \( \langle zx_k \rangle, \langle y_kz \rangle \in F \), then orient the arcs \( \langle za_k \rangle, \langle zb_k \rangle, \langle zc_k \rangle \), and \( \langle zd_k \rangle \) in \( F' \); otherwise, orient the arcs \( \langle a_kz \rangle, \langle b_kz \rangle, \langle c_kz \rangle \), and \( \langle d_kz \rangle \) in \( F' \). Note that, for every \( z \in \tilde{N}(x_ky_k) \setminus N'_k \), the incident arcs of \( z \) in \( F' \setminus F \) are either all incoming or all outgoing arcs in \( F' \). In Figure 6 the orientation \( F' \) is illustrated on two small examples.

![Figure 6](image)

Figure 6: Two examples for the orientation \( F' \) of the graph \( \tilde{G}(e_i), i = k \), of Figure 5, where \( e_k = x_ky_k \).

We will prove that the resulting orientation \( F' \) of \( \tilde{G}(e_k) \) is transitive. To this end, consider two arbitrary arcs \( \langle uv \rangle, \langle vw \rangle \in F' \). We will also prove that \( \langle uw \rangle \in F' \). We distinguish in the following four cases about the arcs \( \langle uv \rangle \) and \( \langle vw \rangle \).

**Case 1.** Let \( \langle uv \rangle, \langle vw \rangle \in F' \). Then clearly \( \langle uw \rangle \in F' \subseteq F' \), since \( F \) is transitive.

**Case 2.** Let \( \langle uv \rangle, \langle vw \rangle \in F' \setminus F \). Then, \( v \neq x_k \) (resp. \( v \neq y_k \)), since \( x_k \) (resp. \( y_k \)) has only one incident arc in \( F' \setminus F \). Furthermore, \( v \notin \tilde{N}(x_ky_k) \setminus N'_k \), since by the construction of \( F' \), the
incident arcs to every vertex of $\tilde{N}(x_ky_k) \setminus N_k'$ in $F' \setminus F$ are either all incoming or all outgoing. Thus, $v \in \{a_k,b_k,c_k,d_k\}$. Now, if $u \in \{x_k,b_k,d_k\}$, then $u$ must belong to $\tilde{N}(x_ky_k) \setminus N_k'$. However, by the construction of $F'$, and since $(uv) \in F'$, it follows that $(x_kw),(b_kw),(d_kw) \in F'$, i.e. $(uw) \in F'$. Similarly, if $w \in \{a_k,c_k,y_k\}$, then $u$ must belong to $\tilde{N}(x_ky_k) \setminus N_k'$. By the construction of $F'$, and since $(uw) \in F'$, it follows that $(ua_k),(uc_k),(uy_k) \in F'$, i.e. $(uw) \in F'$. Finally, if both $u,w \in \tilde{N}(x_ky_k) \setminus N_k'$, then by the construction of $F'$ we see that $(ux_k),(x_kw) \in F$, and thus, $(uw) \in F' \subseteq F'$, since $F$ is transitive.

Case 3. Let $(uw) \in F'$ and $(uv) \in F' \setminus F$. Then, $v \notin \{a_k,b_k,c_k,d_k\}$, since $a_k,b_k,c_k,d_k \in V(G) \setminus V(G)$, and thus, there are no incident arcs in $F$. Furthermore $v \notin x_k$, since $x_k$ has no outgoing arcs in $F' \setminus F$. Thus, $v \in \{x_k\} \cup \tilde{N}(x_ky_k) \setminus N_k'$. In the case where $v = x_k$, we see that $w = a_k$, since $\tilde{N}(x_ky_k)$ is the only outgoing arc from $x_k$ in $F' \setminus F$. Since $(uv) = (x_kw) \in F'$, it follows that $u \notin N_k'$. Furthermore, since $(ux_k),(x_ky_k) \in F'$, it follows that $(uy_k) \in F'$, since $F$ is transitive, and thus, in particular, $uy_k \in E(\tilde{G}(e_k))$, i.e. $u \in \tilde{N}(x_ky_k)$. Therefore, $u \in \tilde{N}(x_ky_k) \setminus N_k'$. Thus, it follows by the construction of $F'$ that $(uv) = (x_kw) \in F'$. In the case where $v \in \tilde{N}(x_ky_k) \setminus N_k'$, it follows that $w \in \{a_k,b_k,c_k,d_k\}$, since $(uv),(vb_k),(vc_k),(vd_k)$ are the only possible outgoing arcs from $w$ in $F' \setminus F$. Then, $(vx_k),(vy_k) \in F'$ by the construction of $F'$, and thus, $(ux_k),(uy_k) \in F$ as well, since $F$ is transitive. It follows that $u \in \tilde{N}(x_ky_k) \setminus N_k'$, and thus, $(uw) \in F'$.

Case 4. Let $(uv) \in F' \setminus F$ and $(uv) \in F'$. Then, similarly to Case 3, $v \notin \{a_k,b_k,c_k,d_k\}$, since $a_k,b_k,c_k,d_k \in V(G) \setminus V(G)$, and thus, there are no incident arcs in $F$. Furthermore $v \notin x_k$, since $x_k$ has no incoming arcs in $F' \setminus F$. Thus, $v \in \{y_k\} \cup \tilde{N}(x_ky_k) \setminus N_k'$. In the case where $v = y_k$, we see that $w = a_k$, since $\tilde{N}(x_ky_k)$ is the only incoming arc to $y_k$ in $F' \setminus F$. Since $(uw) = (y_kw) \in F'$, it follows that $w \notin N_k'$. Furthermore, since $(x_ky_k),(y_kw) \in F'$, it follows that $(x_kw) \in F'$, since $F$ is transitive, and thus, in particular, $x_kw \in E(\tilde{G}(e_k))$, i.e. $w \in \tilde{N}(x_ky_k)$. Therefore, $w \in \tilde{N}(x_ky_k) \setminus N_k'$. Thus, it follows by the construction of $F'$ that $(uv) = (d_kw) \in F'$. In the case where $v \in \tilde{N}(x_ky_k) \setminus N_k'$, it follows that $u \in \{a_k,b_k,c_k,d_k\}$, since $(uv),(vb_k),(vc_k),(vd_k)$ are the only possible incoming arcs to $v$ in $F' \setminus F$. Then $(x_kv),(y_kw) \in F'$ by the construction of $F'$, and thus $(x_kw),(y_kw) \in F$ as well, since $F$ is transitive. It follows that $w \in \tilde{N}(x_ky_k) \setminus N_k'$, and thus, $(uv) \in F'$.

Thus the constructed orientation $F'$ of $\tilde{G}(e_k)$ is transitive. Since $F \subseteq F'$ is a $T$-orientation of $G$ on $N_1,N_2,\ldots,N_k$, it follows that $F'$ is a $T$-orientation of $\tilde{G}(e_k)$ on $N_1,N_2,\ldots,N_k$, and thus also a $T$-orientation of $\tilde{G}(e_k)$ on $N_1,N_2,\ldots,N_k$.

Conversely, let $e_k = x_ky_k$ and suppose that $F'$ is a $T$-orientation of $\tilde{G}(e_k)$ on $N_1,N_2,\ldots,N_k$. We will show that $F'$ is also a $T$-orientation of $\tilde{G}(e_k)$ on $N_k$. Without loss of generality we may assume that $(x_ky_k) \in F'$. Then, since $F'$ is transitive, and since $y_kak_k,x_kbk_k,a_kck_k,b_kdk_k \notin E(\tilde{G}(e_k))$, it follows that $(x_kak_k),(b_kak_k),(b_kck_k),(d_kck_k),(d_kdk_k) \in F'$. First consider a vertex $z \in N_k'$. Then, since $a_kz \notin E(\tilde{G}(e_k))$, since $(x_kak_k) \in F'$, and since $F'$ is transitive, it follows that $(x_kz) \in F'$. Similarly $(yz_k) \in F'$, since $d_kz \notin E(\tilde{G}(e_k))$, and since $(dk_ky_k) \in F'$. Thus $(x_kz),(yz_k) \in F'$ for every $z \in N_k'$. Now consider a vertex $z \in \tilde{N}(x_ky_k) \setminus N_k'$, and suppose that $(x_kz) \in F'$ (resp. $(zx_k) \in F'$). Then, since $x_kck_k,c_ky_k \notin E(\tilde{G}(e_k))$, and since $F'$ is transitive, it follows that $(cx_k),(yz_k) \in F'$ (resp. $(zx_k),(yz_k) \in F'$). Thus for every $z \in \tilde{N}(x_ky_k) \setminus N_k'$, either $(x_kz),(yz_k) \in F'$, or $(zx_k),(yz_k) \in F'$. Therefore $F'$ is also a $T$-orientation of $\tilde{G}(e_k)$ on $N_k$. Thus the restriction of $F'$ on $G$ is a $T$-orientation of $G$ on $N_1,N_2,\ldots,N_k$. This completes the lemma.

After deactivating the edge $e_k$ of $G$, obtaining the graph $\tilde{G}(e_k)$, we can continue by deactivating sequentially all edges $e_{k-1},e_{k-2},\ldots,e_1$ that correspond to the edge neighborhood sets $N_{k-1},N_{k-2},\ldots,N_1$, as presented in Algorithm Deactivate-All. Now the next theorem easily follows by repeatedly applying Lemma 18.
Algorithm 4 Deactivate-All

Input: An undirected graph $G$ with edge neighborhood sets $N_i = \{e_i, N'_i\}$, $i = 1, 2, \ldots, k$
Output: Deactivate all edges $e_i$, $i = 1, 2, \ldots, k$ to produce $\tilde{G}$

1: $P_{k+1} \leftarrow G$
2: for $i = k$ downto 1 do
3: \hspace{1em} $P_i \leftarrow \tilde{P}_{i+1}(e_i)$ \{ $P_i$ is obtained by deactivating the edge $e_i$ in $P_{i+1}$ \}
4: \hspace{1em} $\tilde{G} \leftarrow P_1$
5: return $\tilde{G}$

Theorem 2 Let $G$ be a graph, let $N_i = \{e_i, N'_i\}$, $i = 1, 2, \ldots, k$, be a set of edge neighborhood sets in $G$, and let $\tilde{G}$ be the graph computed from $G$ by Algorithm Deactivate-All. Then, $G$ is $T$-orientable on $N_1, N_2, \ldots, N_k$ if and only if $\tilde{G}$ is transitively orientable.

Since at every step of Algorithm 4, the graph $P_i$ has, by Definition 10, four more vertices than the previous graph $P_{i-1}$, and since each of them can have at most $n$ neighbors in $P_i$, the computation of $P_i$ can be computed in $O(n^2)$ time. Thus, since we iterate for every edge neighborhood set $N_i$, $i = 1, 2, \ldots, k$, the next lemma follows.

Lemma 19 Algorithm 4 runs in $O(nk)$ time, where $n$ is the number of vertices in $G$.

6 A trapezoid graph recognition algorithm

In this section we complete the interpretation of the property of permutation graphs stated in Theorem 1 in terms of transitive orientations. This will enable us to recognize efficiently whether the splitted graph constructed by Algorithm Split-All (Algorithm 2) is a permutation graph with this specific property, or equivalently, due to Theorem 1, whether the original graph is trapezoid. Recall that the class of permutation graphs is the intersection of the classes of comparability and cocomparability graphs, and thus, a graph is permutation if and only if its complement is a permutation graph as well. Furthermore, for every transitive orientation $F$ of the complement $\overline{G}$ of a permutation graph $G$, we can construct (in $O(n^3)$ time, see [6]) a permutation representation $R$ of $G$, such that the line of $x$ lies to the left of the line of $y$ in $R$ if and only if $\langle xy \rangle \in F$.

Before presenting the trapezoid recognition algorithm, we establish the relationship between $T$-orientations and permutation graph representations.

Theorem 3 Let $G$ be a permutation graph, let $e_i = x_iy_i$, $i = 1, 2, \ldots, k$, be a set of edges of the complement graph $\overline{G}$ of $G$, and let $N_i = \{e_i, N'_i\}$, $i = 1, 2, \ldots, k$, be a set of edge neighborhood sets in $\overline{G}$. Then there exists a permutation representation $R$ of $G$, such that for every $i = 1, 2, \ldots, k$, exactly the lines that correspond to vertices of $N'_i$ lie between the lines of $x_i$ and $y_i$ in $R$, if and only if the complement $\overline{G}$ is $T$-orientable on $N_i = \{e_i, N'_i\}$, $i = 1, 2, \ldots, k$.

Proof. Since $e_i = x_iy_i$ is an edge of $\overline{G}$ for every $i = 1, 2, \ldots, k$, $x_i$ is not adjacent to $y_i$ in the complement $G$ of $\overline{G}$. Furthermore, since $G$ is a cocomparability graph (as a permutation graph), we can define for every permutation representation $R$ of $G$ a transitive orientation $F_R$ of the complement $\overline{G}$ of $G$, such that $\langle xy \rangle \in F_R$ if and only if the line of $x$ lies to the left of the line of $y$ in $R$. Then, clearly, the line of a vertex $z$ of $G$ lies in $R$ between the lines of two non-adjacent vertices $x$ and $y$ in $G$ if and only if either $\langle xy \rangle, \langle xz \rangle, \langle yz \rangle \in F_R$, or $\langle yx \rangle, \langle yz \rangle, \langle zx \rangle \in F_R$. This is equivalent to the fact that $z \in I_{F_R}(xy)$. Therefore $I_{F_R}(x_iy_i) = N'_i$ for every $i = 1, 2, \ldots, k$.
if and only if for every $i = 1, 2, \ldots, k$, exactly the lines that correspond to vertices of $N'_i$ lie between the lines of $x_i$ and $y_i$ in $R$. Thus, if there exists such a permutation representation $R$ of $G$, then $F_R$ is a $T$-orientation of $\overline{G}$ on $N_1, N_2, \ldots, N_k$, i.e. $\overline{G}$ is $T$-orientable on $N_1, N_2, \ldots, N_k$.

Conversely, suppose that $\overline{G}$ is $T$-orientable on $N_1, N_2, \ldots, N_k$, and let $F$ be a $T$-orientation of $\overline{G}$ on these neighborhood sets. By the definition of a $T$-orientation, $F$ is in particular a transitive orientation of $\overline{G}$. Thus, we can construct a permutation representation $R$ of the complement graph $G$ of $\overline{G}$, such that for any two non-adjacent vertices $x$ and $y$ in $G$, the line of $x$ lies to the left of the line of $y$ in $R$ if and only if $(xy) \in E[6]$. Then, clearly, the line of a vertex $z$ lies between the lines of $x$ and $y$ in $R$ if and only if $z \in I_F(xy)$. Therefore, since $\overline{G}$ is $T$-orientable on $N_1, N_2, \ldots, N_k$ (i.e. $I_F(x_iy_i) = N'_i$ for every $i = 1, 2, \ldots, k$), it follows that exactly the lines that correspond to vertices of $N'_i$ lie between the lines of $x_i$ and $y_i$ in $R$, for every $i = 1, 2, \ldots, k$. 

Now, we are ready to present our recognition algorithm of trapezoid graphs. Our algorithm uses an existing algorithm that we now review. McConnell and Spinrad [9] (see also [12]) developed a linear time algorithm for finding an ordering of the vertices of a given graph $G$ with the property that this ordering is a transitive orientation, if $G$ is a comparability graph. If the given graph $G$ is not a comparability graph, then the ordering produced by their algorithm is an orientation, but it is not transitive. The fastest known algorithm to determine whether a given ordering is a transitive orientation requires matrix multiplication, currently achieved in $O(n^{2.376})$ [4]. However, similarly to [9], we do not need to confirm that our orderings are transitive orientations. In particular, given an orientation of a graph $G$ and an orientation of its complement $\overline{G}$, we can check in linear $O(n + m)$ time whether these two orientations produce a permutation representation of $G$, where $n$ and $m$ denote the number of vertices and edges of $G$, respectively. We now present our trapezoid graph recognition algorithm (Algorithm 5). The correctness of this algorithm is presented in Theorem 4; the timing analysis is established in Theorem 5.

**Theorem 4** If $G$ is a trapezoid graph, then the Recognition of Trapezoid Graphs Algorithm (Algorithm 5) returns a trapezoid representation of $G$. Otherwise, it announces that $G$ is not a trapezoid graph.

**Proof.** Let $G = (V, E)$ be an undirected graph with vertex set $V = \{u_1, u_2, \ldots, u_n\}$, let $G^*$ be the graph constructed by Algorithm Augment-All (Algorithm 1) from $G$, and $G^\#$ be the graph constructed by Algorithm Split-All (Algorithm 2). Let $u_{i,5}, u_{i,6}$ be the vertex derivatives in $G^\#$ that correspond to vertex $u_i$, $i = 1, 2, \ldots, n$, in $G$. Furthermore, let $\tilde{N}_i, i = 1, 2, \ldots, n$, be the set of intermediate vertices of $u_{i,5}, u_{i,6}$ computed by Algorithm Intermediate-Lines (Algorithm 3).

First suppose that $G$ is a trapezoid graph. Then, due to Theorem 1, $G^\#$ is a permutation graph with a permutation representation $R^\#$, such that $\tilde{N}_i$ is exactly the set of vertices of $G^\#$, whose lines lie between the vertex derivatives $u_{i,5}$ and $u_{i,6}$ in $R^\#$, for every $i = 1, 2, \ldots, n$. Since $G^\#$ is a comparability graph (as a permutation graph), the orientation $F_1$ of $G^\#$ computed in line 5 of the algorithm is a transitive orientation of $G^\#$ [9]. Furthermore, in particular, the complement $\overline{G^\#}$ of $G^\#$ is $T$-orientable on $N_1, N_2, \ldots, N_n$ by Theorem 3, where $N_i = \{u_{i,5}, u_{i,6}, \tilde{N}_i\}$, $i = 1, 2, \ldots, n$, are the edge neighborhood sets of $\overline{G^\#}$ computed in line 7. Therefore, $\overline{G}$ is transitivity orientable by Theorem 2, and thus the orientation $F_2$ of $\overline{G}$ computed in line 9 is transitive [9].

Moreover, due to the sufficiency part of the proof of Lemma 18, $F_2$ is also a $T$-orientation of $\overline{G}$ on $N_1, N_2, \ldots, N_n$. Thus, since $\overline{G^\#}$ is an induced subgraph of $\overline{G}$, the restriction $F_2 = F_2|_{\overline{G^\#}}$ of $F_2$ to $\overline{G^\#}$ is also a $T$-orientation of $\overline{G^\#}$ on $N_1, N_2, \ldots, N_n$, and in particular $F_2$ is also a transitive orientation of $\overline{G^\#}$. Therefore, since both $F_1$ and $F_2$ are transitive orientations of $G^\#$.
**Algorithm 5** Recognition of Trapezoid Graphs

**Input:** An undirected graph $G = (V, E)$ with vertex set $V = \{u_1, u_2, \ldots, u_n\}$

**Output:** A trapezoid representation of $G$, or the announcement that $G$ is not a trapezoid graph

1. Construct the augmented graph $G^*$ from $G$ by Algorithm Augment-All (Alg. 1) \{ $G^*$ has $5n$ vertices \}
2. Construct the splitted graph $G^\#$ from $G^*$ by Algorithm Split-All (Alg. 2) \{ $G^\#$ has $6n$ vertices \}
3. Let $u_{i,5}, u_{i,6}, i = 1, 2, \ldots, n$, be the vertex derivatives in $G^\#$
4. Compute the sets $\hat{N}_i$, $i = 1, 2, \ldots, n$, by Algorithm Intermediate-Lines (Alg. 3)
5. Compute an ordering $F_1$ of $G^\#$ by [9]
6. Compute the complement $\overline{G^\#}$ of $G^\#$
7. Compute the edge neighborhood sets $N_i = \{u_{i,5}u_{i,6}, \hat{N}_i\}, i = 1, 2, \ldots, n$, in $\overline{G^\#}$
8. Compute the graph $\tilde{G}$ from $\overline{G^\#}$ and $N_i$, $i = 1, 2, \ldots, n$, by Algorithm Deactivate-All (Alg. 4)
9. Compute an ordering $F_2$ of $\tilde{G}$ by [9]
10. $F'_2 \leftarrow F_2_{\overline{G^\#}}$ \{ Compute the restriction of $F_2$ on $\overline{G^\#}$ \}
11. if the orderings $F_1$ and $F'_2$ do not represent $G^\#$ as a permutation graph (see [12]) then
   12. return “$G$ is not a trapezoid graph”
13. else
14. Compute a permutation representation $R^\#$ of $G^\#$ from the orderings $F_1$ and $F'_2$ by [6]
15. Replace in $R^\#$ the lines of the derivatives $u_{i,5}, u_{i,6}, i = 1, 2, \ldots, n$, by a trapezoid $T_u$, defined by these lines
16. Remove the lines of the vertices $\{u_{i,1}, u_{i,2}, u_{i,3}, u_{i,4}\}$, $i = 1, 2, \ldots, n$
17. Let $R$ be the resulting trapezoid representation
18. if $R$ is a trapezoid representation of $G$ then
   19. return $R$
20. else
21. return “$G$ is not a trapezoid graph”

and $\overline{G^\#}$, respectively, they represent $G^\#$ as a permutation graph (see [12]). Thus, we can compute by [6] a permutation representation $R^\#$ of $G^\#$ from the orderings $F_1$ and $F'_2$, such that for every $i = 1, 2, \ldots, n$, exactly the lines that correspond to vertices of $\hat{N}_i$ lie between the lines of $u_{i,5}$ and $u_{i,6}$ in $R^\#$. Then, similarly to the proof of Theorem 1, we can replace in $R^\#$ the lines of the derivatives $u_{i,5}$ and $u_{i,6}$, $i = 1, 2, \ldots, n$, by a trapezoid $T_u$, defined by these lines, and remove the lines of the vertices $u_{i,1}, u_{i,2}, u_{i,3}, u_{i,4}$, obtaining a trapezoid representation $R$ of $G$, as returned in line 19.

Now suppose that $G$ is not a trapezoid graph. If either or both of $F_1$ and $F'_2$ are not transitive orientations of $G^\#$ and $\overline{G^\#}$, respectively, then the algorithm correctly concludes in line 12 that $G$ is not a trapezoid graph. Suppose that $F_1$ and $F'_2$ are both transitive orientations of $G^\#$ and $\overline{G^\#}$, respectively (and thus $G^\#$ is a permutation graph), but $F_2$ is not a transitive orientation of $\tilde{G}$. Then by Theorems 1, 2, and 3, $G$ is not a trapezoid graph, as confirmed in line 21 of the algorithm. This completes the proof of the theorem. ■

**Theorem 5** Let $G = (V, E)$ be an undirected graph, where $|V| = n$ and $|E| = m$. Then the Recognition of Trapezoid Graphs Algorithm (Algorithm 5) runs in $O(n(n + m))$ time.

**Proof.** The first two lines of the algorithm each require $O(n(n + m))$ time by Lemmas 8 and 12, respectively. Furthermore, the computation of all the sets $N_i$, $i = 1, 2, \ldots, n$, can be done in $O(n^2)$ time by Lemma 16. The complement $\overline{G^\#}$ of $G^\#$ in line 6 can clearly be
computed in $O(n^2)$ time. Then the graph $\bar{G}$, which is a supergraph of $G^\#$, can be computed in $O(n^2)$ time by Lemma 19, since there are in total $k = n$ edge neighborhood sets $N_i = \{u_{i,5}u_{i,6}, N_i\}$, $i = 1, 2, \ldots, n$. As pointed out in the preamble to the algorithm, we can compute the ordering $F_1$ of $G^\#$ in line 5 (resp. the ordering $F_2$ of $\bar{G}$ in line 9) in linear time in the size of $G^\#$ (resp. of $\bar{G}$) [9], i.e. in $O(n + m)$ time (resp. in $O(n^2)$ time). Moreover, the restriction $F_2|_{G^\#}$ of $F_2$ on $G^\#$ can be clearly done in $O(n)$ time, just by removing from $F_2$ all vertices of $\bar{G} \setminus G^\#$. Then the permutation representation $R^\#$ can be computed in $O(n^2)$ time by [6]. The replacement of the lines of the derivatives $u_{i,5}$ and $u_{i,6}$ by a trapezoid $T_{ui}$ in $R^\#$, $i = 1, 2, \ldots, n$, as well as the removal of all vertices $\{u_{i,1}, u_{i,2}, u_{i,3}, u_{i,4}\}$, $i = 1, 2, \ldots, n$, can be now performed in $O(n)$ time. Finally, the determination of whether $R$ is a trapezoid representation of the given graph $G$ can be simply done in $O(n^2)$ time, thereby yielding an overall time complexity of $O(n(n + m))$. ■

7 Concluding Remarks

In this paper we have shown that the concept of vertex splitting can be used to recognize trapezoid graphs in $O(n(n + m))$ time. The algorithm transforms a given graph $G$ into a graph $G^\#$ that is a permutation graph with a special property if and only if $G$ is a trapezoid graph. In [11] it was shown that vertex splitting can be used to show that the recognition problems of tolerance and bounded tolerance graphs are NP-complete. It would be interesting to see whether vertex splitting can be used to settle the longstanding questions of the recognition status of both $PI$ and $PI^*$ graphs. As mentioned in the introduction, both families lie strictly between permutation and trapezoid graphs.
