Evaluating an Interprofessional Education Curriculum: A theory informed approach

Introduction

Few interprofessional education (IPE) curricula¹ for integration within core profession-specific programmes have been fully described and those that have vary because of the need to accommodate local arrangements within participating health and social care programmes (Barratt, et al. 2003; O’Halloran, et al. 2006; Barr, 2007; Curren, et al. 2010). Despite this, there is strong agreement about the goal of preparing students for future collaborative practice (Freeth, et al. 2005; Gilbert, 2005), the intended learning outcomes needing to align to health and social care policy and professional body requirements (Thistlethwaite & Moran, 2010; World Health Organisation, 2010; Thistlethwaite, 2012) and for early theoretical understandings to be applied later within practice learning (Thistlethwaite & Nisbet, 2007). However, there is limited understanding on what works well and what to avoid, partly because of the relative lack of discussion between IPE curriculum developers of the theoretical or conceptual frameworks underpinning the rationale, structure and evaluation of curriculum design (Reeves et al. 2011; Reeves & Hean, 2013).

One of the challenges for IPE research is to articulate theoretically informed evaluation models which can begin to clarify the constituent events and interactive processes that lead

¹ ‘Curriculum’ here means a series of different learning activities designed to advance learning over time. The word programme is used interchangeably with curriculum in this paper. IPE refers to interactive learning between learners from different professions as defined in the World Health Document of 2010.
to new knowledge and understandings (Frye & Hemmer, 2012). The term evaluation is used here to refer to well designed, valid and planned educational research rather than a post-learning measure used solely for educational quality purposes (De Bere, 2010). Generally, reported IPE evaluations are of individual initiatives, which form part of a curriculum, rather than evaluations of an entire curriculum. This partial means approach a failure to consider the entire programme which would present a better understanding of how to constructively align IPE within core profession-specific curriculum at both pre and post-registration level (Biggs, 1993). A curriculum with misguided non-aligned learning elements, be these entire modules/units/placements or small events within modules/units/placements, may fulfil their intended learning outcomes and be enjoyed by students, but fail to build and affirm an advancement towards the goals of IPE. We would argue that curriculum development requires an understanding of the whole learning journey to illuminate student engagement, highlighting IP events which progress learning and those with the least impact, while suggesting changes and identifying possible gaps. Lack of clarity on how learning helps to achieve curriculum goals is not unique to IPE; for example, medical education continues to debate ‘best evidence’ for its curriculum and as such seeks constant affirmation of how to proceed (Harden & Lilley 2000; Regehr, 2004; Wolf 2000; Hammick, 2005), whilst seeking out conceptual frameworks to address complex problems and to develop possible solutions (Bordage, 2009)

The curriculum evaluation reported here, was jointly established by three Higher Education Institutions (HEIs) with different histories, each educating different health and social care professionals. One university has a medical school with social work and operating
department practitioner (ODP) programmes, another programmes in pharmacy, speech and language therapy, social work, audiology, nursing (all branches) and midwifery, and the third, paramedics, occupational therapists and nursing education. Curriculum design was theoretically informed, combining knowledge of theories on social behaviour in groups from psychology and sociology and ideas about applied learning (Anderson, et al. 2014).

Within the complexity of IPE curriculum where much is happening reflecting the multidimensionality so often found in social sciences and generating knowledge depends upon understanding the qualitative nature of human relationships, at least as much as on the application of quantifiable measures of learning gain and consolidation (Wong, et al. 2012).

For this reason we used an evaluation model that would enable recognition of how the new learning was received by students, faculty and practice. We recognised that change would result from the dynamic interplay of factors relating to each learning moment along the curriculum journey. Evaluation models we could have used include the ‘CIPP (context/input/process/product)’ model (Frye and Hemmer (2012, p. 296), and Coles and Grant’s model which sees effective curriculum as three components which must align: the curriculum as agreed on paper, as realised in-action and experienced by the students (Coles, 1985).

Our choice was the Biggs’ 3 P Model, which enables consideration of the presage, process and product or outputs of student learning, the teachers journey in planning delivering and assessing outcomes and the patient story of engagement in the learning (Biggs 1993), and used elsewhere (Freeth, et al. 2005; Reeves & Freeth, 2006). The 3P model ‘represents an integrated system’ (Biggs,
1989; Biggs, 2002), positing that the eventual outcomes of student learning depends on the interaction between the ‘presage’ factors (student characteristics, teaching context and preparation) and ‘process’ factors (student orientation to/engagement with learning, teaching style and pedagogic content). The model’s theoretical stance derives from complexity theory used previously to explore IPE because of the additional layers of stakeholder views across different professional curriculum (Barr, 2013). In addition we applied the Kirkpatrick typology of education outcomes which have been modified for IPE, mindful not to be constrained by only these levels so that we would consider all the consequences of the learning on all participants including the unanticipated (Barr, et al. 2005; Yardley & Dornan, 2012).

This paper outlines our meta-analysis of our IPE evaluation made in order to retrospectively reflect and identify the key messages about what had progressed interprofessional learning (IPL) in one locality. In so doing we aim to encourage theoretically informed evaluation approaches to develop clarity about improving IPE curriculum. With hindsight we might have done things differently, asking more theoretically informed questions for rigorous testing because we failed to appreciate the complexity of the undertaking (Frye & Hemmer, 2012). In this we are not alone as authors continually request conceptual frameworks to help illuminate best practice (Bordage, 2009). To this end, increasingly sophisticated frameworks for evaluation are being developed (Frye & Hemmer, 2012).

Our Interprofessional Curriculum.

Policy in the UK, (DOH, 2000) propelled the establishment of a local group to develop our IPE strategy; a theoretical stance to support concrete developments in teaching and learning
was drawn from psychology; in particular, utilising the contact hypothesis (Allport, 1954), with attention to its adaptations for learning conditions within IPE to challenge traditional stereotypes (Carpenter, 1995; Carpenter & Hewstone 1996). The design of individual learning events was influenced by educational theories relating to the process of learning as adhered to by cognitive constructivists such as Piaget (1973) extolling a staged process of knowledge construction. Additionally, the process of social learning was considered, with learning communities in practice supporting medical curriculum primed for later IPE arrangements (Wenger, 1998; Anderson, et al. 2003). Social constructivist theorists such as Bandura (1977) who place emphasis on constructing meaning through learning with others in a social context were utilised. The curriculum was designed to encompass introductory teacher-led learning, moved on to incorporate models of adult learning utilising self-directed learning processes for both personal and group reflection (Knowles, 1978). We used learning triggers for self-directed problem based learning which were socially mediated through small-group study sessions allowing expansive (‘deep’) learning to emerge (Briggs & Myers, 1995; Engeström, 1987; Regehr, 2004; Bleakley, 2006).

The separate HEIs, bound by different curriculum committees, and different professional programmes overseen by respective professional bodies, agreed a curriculum framework entitled the ‘Three Strand Model’, of IPL (Smith & Anderson, 2007; Anderson, et al. 2014). This assured IPL was woven within existing modules within each respective school and it had a the place in the curriculum, first, second, third year, varied where programmes ran beyond three years, but always reflected the beginning, middle and end periods of study. IPL events were designed to be integrated into the programme framework; and ran for one, two, or up
to four days. The final IPE curriculum progressed from early conceptualisations of what it
means to be interprofessional, delivered in classroom settings (strand one, one day)
followed by practice learning with patients/service users (strand two, two-days) and further
opportunities to work in practice with additional workshops and simulations (strand three,
one lasting four days with others lasting one day and where students attend more than one
event) (Figure 1).

Insert Figure 1 Here

A competence measure was used to assess student IPL because of its familiarity to the
majority of local health and social care curriculum developers. In this way learning outcomes
were established for assessing the development of knowledge, skills, attitudes and
behaviours. All disciplines agreed that students should complete an Interprofessional
Personal Portfolio to collate their reflections on their learning journey towards
interprofessional competence. Students were given theoretical models to guide their
reflections submitted as short essays after each IPL event. The reflections have now been
analysed and reveal how the learning triggered new knowledge and skills and framed future
intended behaviours (Domac, et al. 2015). In addition, the portfolio contained profession-
specific assessments to map against their various professional bodies’ requirements for
team working and collaborative practice.

The Evaluation Strategy

We employed a regional evaluator, funded by the local health authority, from the outset,
seeing this as integral to the development and sustainability of the local IPE curriculum,
through prospective accounts of implementation and impact. The evaluation programme was supported by a regional research committee with representatives from each University, funders and drawing on recognised external expertise. Ethical permission for the curriculum evaluation was obtained from the outset in 2005 (COREC; 05/Q2502/104).

Our evaluation model (Figure 2) considered the ‘assumptions of linear relationships between program elements and desired outcomes’ (Frye & Hemmer, 2012), while paying particular attention to the complexity of the views of all stakeholders, students and educators, service and patients, to help us perceive how students advanced their knowledge, skills and attitudes and the impact of IPL. Each individual learning programme was evaluated against the Kirkpatrick outcomes levels (Table 1).

INSERT Figure 2 HERE

INSERT Table 1 HERE

The evaluation methodologies included mixed methods and cyclical data collection in prospective action-based qualitative studies (Table 2). We used conventional ‘output/outcome’ evaluative methods, together with those which seek to look inside the ‘black box’ (Carpenter & Dickinson, 2008) in order to gain a better sense of the processes of joint learning and their implications for co-production of knowledge. Each element of the overall IPE programme was extensively evaluated to ensure the continuous appropriateness and continuity of learning. Different methodologies were implemented at different phases of the curriculum evaluation.
Despite a clear rationale for designing our teaching based on theories of learning and a clear theoretical rationale for the evaluation, we did not test theory in its application. In other words, we failed to address some key questions, for example, how would different teaching methods advance learning towards understanding interprofessional working? What are the most effective programmes and why? How does contact make learning different? Why and how does IPE advance learning? What are the cost implications of this new curriculum theme? What are the impacts upon each school and HEI? Our mistake was unrelated to methodological choices, as these were wide ranging to gather quantitative and qualitative data, but rather in our focus on the overall programme aims. Thus our insights emerged iteratively by applying a theoretical approach in-action.

The Outcomes from the Evaluation

Re-examining the evaluations highlighted what students were learning, why some teaching approaches were better received than others and various issues from the experiences of all stakeholders. Below we set out how, by applying theoretical insights, albeit retrospectively, we made sense of what was happening.

Considering first the ‘presage factors’ we looked to see what issues constrained or successfully progressed the IPE curriculum. Evaluation using the RIPLS questionnaire to assess student readiness for IPL failed to reveal any substantive differences between the
students prior to embarking on IPE for the first time (Table 3, exemplar 1) (Parsell &
Bligh, 1999). Following the early strand one learning practical concerns were raised, such as
the teaching environment being often marginalised as IPE competed with established
schedules which received the best teaching rooms, teaching support and shared payment
for teaching resources.

Of the process factors the approaches to teaching for learning in early strand one, proved
most challenging and a number of issues required theoretical consideration. These
difficulties related to the development of professional identity which was largely
uninformed when the students first met and as they struggled to profess strong associations
to professions they knew little about. These tensions ran alongside the completion of the
learning activities. Stereotyping and emotional reactions permeated their evaluations and
reflective writing, similar to those found in other programmes (Table 3, Exemplar 1) (Hean,
et al. 2006). The formation of ‘in-groups’ and ‘out-groups’ as described by social identity
theory (Tajfel & Turner (1986) and the social gain from joining professional groups as
explained by social capital theory were key to helping us explore these findings (Bourdieu,
1997). To address these problems teaching content changed to engage students in
reflective exercises to unpack some basic understandings of team working in health and
social care using theoretical tools to explore student emotions and attitudes. For example,
exploring what is meant by emotional intelligence and why we naturally form stereotypes
(Goleman, 1998; Druskat & Wolff, 2001).
We identified the need for deeper and richer appreciation of how to manage small group IPE facilitation. This led to the design and delivery of a new faculty development opportunity (Table 3, Exemplar 2). This explored psychological and sociological theories applied to human behaviours in groups, the sensitivities of interprofessional groups and the management of group dynamics. This theoretical framework helped to explain how some of the early IPE faculty sceptics changed their negative attitudes towards IPE to favour and value the aspirations of this learning. Our evaluations identified that the sceptics re-evaluated their attitude construction, explained by cognitive dissonance theory (Table 3, Exemplar 3) (Festinger, 1957). The sceptic teachers were surrounded by positive role model teachers and students who were clearly enjoying the IPE and as a result came to change their cognition to favour and value this form of teaching. Clearly the first steps in curriculum design required detailed understanding of theories of group behaviour. Further, despite initial concerns the value of early classroom learning was subsequently highlighted against the evaluations across the whole curriculum, as the later findings identified students’ readiness to engage in IPL events in practice because of this early learning (Table 3, Exemplar 4).

In addition explanation of other poor strand one evaluations related to the alignment of the new IPE learning theme within the corpus of the main professional curriculum and integration of students’ prior experiences. It became clear, and educators confirmed this finding, that the new learning was not always explained and integrated with profession-specific curricula, and students were heard saying ‘why am I here?’ (Biggs, 2002).
The most positive evaluations were for experiential learning in clinical teams with direct patient/service user involvement, based on a modified Kolb learning cycle which enabled constructivist learning through experience, reflection and analysis (Table 3, Exemplar 5). The Strand Two ‘Health in the Community’ course was modified to accommodate the widening access of different student professions. Patient selection had to move on to those where the interplay of health and social care was evident and involved a broader range of professions including the voluntary sector. Reaching these understandings of practice-learning required many cycles of evaluations and this empirical research was invaluable (Table 3, Exemplar 4).

Our practice-based learning in Strand Three has been adapted for community and hospital teaching; for example, in stroke and rehabilitation wards and in community mental health units. During these developments action learning approaches engaged all stakeholders in assessing the impact of the teaching experience on student learning and building on these insights (Table 3, Exemplar 6). In particular we have spent time listening to patients/service users and have been able to engage them within the teaching team (Table 3, Exemplar 7). This enabled us to grow practice-based communities of learning between participating professions, patients/service users and carers, learning facilitators and academics (Wenger, 1998). These have ensured sustainability of this work, with community organisations now employing community IPE tutors.

Of the product factors the outcome of the evaluation were mapped against the Kirkpatrick framework and wider consequences were collated. Pre- and post-test questionnaire scores identified student learning (Kirkpatrick level 2b) and the additional free text comments have confirmed student reactions (Kirkpatrick level 1) and intentions for future behaviour (working towards Kirkpatrick Level 3). Portfolio assessments offered insights into the
students’ subjective experience of IPE and their competence development. In-depth
interviews and focus groups with students and educators were invaluable. Surveys, for
example, demonstrate high levels of satisfaction and knowledge gain; on the other hand,
this was balanced by more nuanced evidence provided through focus groups and interviews
with students, patients and other stakeholders. The results prompted us to revise our
teaching inputs and approach where certain disciplines had identified concerns, such as
feeling marginalised: “I got there and the doctor or nurse in charge, she was always talking
to the two medical colleagues”, (Table 3, Exemplar 8, p.236). This aspect of our evaluative
work enabled us to identify differences of perception and the challenge of dealing
constructively with problems arising from preconceptions and stereotypes. For example; ‘I
do think this course gave a very good chance to see how social workers do and what I can as
a future clinician expect them to help me with as we work in a team, which I think was a very
good experience’ (Table 3, Exemplar 8, p236).

Of particular value and very positively received was the opportunity to engage students in
shaping and designing learning (Table 3, Exemplar, 9). Discovering how students frame their
thinking came from comparative studies using uni and interprofessional groups (Table 3,
Exemplar 10). Student practice-based work on patient analysis showed how the
interprofessional student teams had an impact on patient care and organisational practice.
The outcomes of this learning reached the highest level of the Kirkpatrick framework,
affirmed in feedback from practitioners and patients (Table 3, Exemplar 11, 12). Here we
learnt that towards the end of their programmes interprofessional student teams can take
on modified clinical responsibilities overseen by qualified staff providing a powerful vehicle
for student learning and for supporting practice. Figure 3, relates to what is written above.
Strengths and Weaknesses of the evaluation tools

One of the strengths of this evaluation model is the combination of methods and the triangulation of the different evaluation tools applied to different aspects of curriculum development, namely presage, process and product. To examine outputs against the Kirkpatrick evaluation framework we needed to apply a range of tools. For example, the IPE portfolio offered invaluable feedback to curriculum committees in revealing the subtle step-by-step learning across the curriculum (Table, 3 Exemplar 13). As Carpenter and Dickinson (2008) argued, there is value in linking different aspects of the overall evaluation in a ‘stepwise’ approach, so that learner attributes are linked with measures of programme integrity and impact and these in turn linked with subsequent outcomes in terms of practitioner behaviour and patient/service user benefits (Carpenter, et al. 2007). Clearly applying different conceptual frameworks can help to sharpen understanding and move the curriculum to the next level of analysis; and this is further supported by the argument of Frye and Hemmer (2012) who indicate that a combination of methods of evaluation may be best suited to both the complexity of the field of practice represented by IPE, and to the integration of varying theoretical perspectives.

Our evaluation design provided the opportunity to follow the development of both novice and experienced IPE faculty members along their learning journey. Insights included the challenges for faculty development, such as training in the management of small group IPL
facilitation and understandings of the value added aspects of IPE for health and social care professional programmes, while highlighting the benefits for educators working on educational design and delivery for advancing personal and professional development (Table 3, Exemplar 14). In addition the burden of engagement with IPL as additional to core uni professional learning resulted in an increased work-load for the IPE facilitators and new management structures were needed to plan and trouble shoot so that increasing workloads could be reconciled and support found to ensure that the benefits for personal and professional development were not compromised (Anderson, et al. 2014).

Discussion

The report of our evaluation of an entire IPE curriculum takes place after several years of on-going cyclical delivery. We used the conceptual framework model elaborated by Biggs, considering presage, process and product in constructing an approach which linked concrete evidence obtained in advance of and at the point of delivery (evaluation material), with more discursive and wider-ranging follow up, which probed each step of the curriculum, and was then more comprehensively articulated with the creative application of theory. To consider impact in more detail we aligned outcomes to the Kirkpatrick Model (Carpenter & Dickinson, 2008). Not all of our methods have been implemented as comprehensively as we would like, with limited resources. We have, though, demonstrated the overall practicality and potential added value of an evaluation strategy which consciously and pro-actively links the stages in the process of preparing and delivering IPE, and the outcomes from a range of stakeholder perspectives (Yarbrough et al, 2011). This,
we argue, provides a degree of empirical validation for those systemic models of evaluation
developed by Biggs (1989) and others (Kirkpatrick, 1998; Frye & Hemmer, 2012).

We are not alone in trying to advance our understanding of IPE through considering the
application of theory (Reeves & Hean, 2013). Our results show that theory is a valuable tool
in the curriculum design and to synthesise and help explain our evaluation findings.
However, overall we found it challenging to limit ourselves to testing out one theoretical
model and argue that solutions for both evaluating and enhancing IPE rest with sequential
application of different conceptual frameworks as Frye and Hemmer argue persuasively
(2012). It is clear that there are only positive advantages to using an evaluation framework
(Figure 2) which focuses on all elements of the learning experience from preparation to
‘product’, combined with considering all stakeholder views - students, teachers and patients
(Biggs, 1993).

One of the most important questions for those who establish pre-registration IPE is what
makes for a good curriculum threaded throughout a profession-specific programme? We
found that a progression of events starting with theoretical appreciation and moving into
placement learning to examine the complexity of modern team working in a range of clinical
settings is required. The most positive evaluations are for student engagement in practice
(Anderson & Thorpe, 2014). The learning with and from the patient/service user’s voice and
professional role models can develop a pathway of learning that appears to arrive at its goal
of sensitising and equipping future practitioners for collaborative working. However,
preparation with theoretical application must come early.
There are still many unanswered questions relating to vertical and horizontal curriculum alignment and robust assessment methodologies that can be used to determine progression towards professional registration. We remain somewhat constrained in seeking to determine what learning moments influence student learning towards being ‘truly collaborative’ and or ‘workforce ready’ as envisaged by the World Health Organisation in 2010 (WHO, 2010); but we support the proposition, strongly endorsed in our study by students across the range of professional disciplines, that learning together in practice is essential. Despite the successes we have claimed, we recognise that IPL is (or should be) consolidated while in practice.

The approach to education evaluation is becoming increasingly sophisticated but its progress is by no means complete. More insight is needed into the place of assessment and the role of validated measures of observable team-based behaviours. Although some tools for this are available there is no agreed measure and management for valid and reliable results (Thistlethwaite, 2012). We are also aware of the continuing challenges of demonstrating sustainable long term gains. The integrated evaluation framework that emerged from the process reported here represents a significant achievement. Nevertheless, it could have been a more straightforward process had we adopted a validated approach such as the CIPP model (Frye & Hemmer, 2012) from the outset, and tested the research questions being asked by the World Health organisation concerning IPE (Gilbert, 2014)
We are not presenting our evaluation design as a fait accompli, rather we look to share these experiences to propel the IPE community to consider whole and comparative programme evaluation using conceptual frameworks that can help to illuminate what works well, and why, and at the same time, takes forward IPE research. Indeed, although it was clearly not originally formulated as such, we could perhaps argue that our developing strategy has amounted to a form of ‘meta-evaluation’ (Yarborough et al. 2011), whereby each component is reviewed both in its own right, and in terms of its potential to contribute to the overall picture.

We were able to support the employment of our programme evaluator for part of this period, and some small grants were from the Higher Education Academy and other sources. Indeed, the small scale and diffuse nature of the funding has been beneficial in many ways, in enabling us to develop our overall strategy piecemeal and by a more or less logical progression. The programme has remained in place since 2005 but is currently under review with in-coming senior HEI leads. Further work is planned (patient safety/simulation activities) and on-going cyclical reviews may bring changes.

Conclusion

Comparisons of medical education curriculum approaches are beginning to illuminate the benefits of different learning approaches and curriculum designs (Schmidt, et al. 1996). Although rigorous experimental evaluations designs such as Randomised Control Trials might identify the best curriculum models, pre-registration curriculum, professional body requirements militate against using such designs. However, we can use multiple evaluation methodologies which reveal curriculum effects on participants and faculty. We suggest that
those setting out to plan or re-design IPE curriculum establish clear and systematic research questions for their curriculum, underpinned these by theory at the outset, and test both questions and the chosen systematically as their enquiries progress.

**Practice Points**

- Underpin curriculum evaluation of interprofessional education with a theoretical approach
- Assess IPE curriculum as a whole not as segmented learning pieces to advance understandings of what works and why.
- Apply the concept of Biggs 1993, presage, process and outputs model to consider curriculum issues
- Involve all stakeholders in any curriculum evaluation, students, faculty and patients
- Take an open and reflective approach to theory choices when making education and evaluation decisions.
References

Figure 1

The Framework for the curriculum

Strand Three
Patient/Service user centred learning.
Practice-based IPL in mental health, care of the older person, disabled people.
Patient safety workshops & simulations.

Aims of Strand Three
- To provide context(s) for applying developing working competence to practice
- Analyse and reflect on challenging real situations to consider solutions to improve team based care
- To develop an understanding of how individual professional competencies complement those of other professions
- To develop an understanding of team working in modern health and social care and education.

Strand Two
Patient/Service user centred IPL.
Students learn with and from patients in community settings.

Aims of Strand Two
- To apply the theoretical basis of team working
- To gain a richer appreciation of roles and responsibilities of practitioners
- To analyse effective collaborative team practice
- To consider your future contribution to person centred team working

Strand One
Classroom-based
Introduction to team working:
Theories.

Aims of Strand One
- To explore what is meant by team working in health and social care
- To begin to apply a theoretical understanding to team work
- To become familiar with your chosen profession and others
- To consider the outcomes of team working for promoting person-centred collaborative care.
Evaluation Matrix Framework

Input
- Presage
  - Students
    - 2005 year one study group
    - Validated measures
  - Stakeholders
    - Faculty Members, (academic and practice educators), Practitioners and patients
    - Cost of participation
  - Effects of participation
    - a) Experienced teachers and novice educators
    - b) Practitioners and patients

Process
- The IP experience

Output
- Product
  - Kirkpatrick Outcome Levels
  - Advanced Patient Care
    - Assessments
    - Practice behaviour
      - Personal to stakeholder
      - Higher Education Institution
      - Students

Figure 3: A flow diagram to illustrate the evaluation processes, application of theory to curriculum change or for faculty development

Curriculum trajectory

Key Findings of the Evaluation Process
Repeted research cycles

- Stereotype behaviours identified
- Graduates unhappy to learn alongside undergraduates
- Facilitator variability and skill base
- Shorter events for graduates with prior experience of healthcare practice
- Confirmation of teaching materials that stimulate learning

Application of theory to Educational Research and curriculum adaptations

- Sociological/psychological theories of individual behaviour in groups
  - Establish faculty development e.g. IPE facilitator training
  - Explore learning content to consider student attitude formation
  - Separate graduates from undergraduates
  - Enhance learning that values graduates

Prior strand evaluations influence and align with the next

- Classroom based (strand one). Students who miss this step arrive unprepared for the complexities of learning with patients
  - Students value IPE in practice with patients
  - Challenges of social work students perceptions of care versus healthcare students
  - Consideration of patients' needs (invite patients to steering groups) and practitioner needs

- Time invested in listening to patients and involving them in IPE development
  - Linking policy and curriculum drivers for patient safety
  - Highly valued learning by students
  - Preparation for some students unfamiliar with some clinical environments
  - Students framing their thinking differently 'us together' and not 'I alone'

- Research informs curriculum

- Endorse the benefits of the Kolb learning cycle for all stakeholders. Use students reflections on entire curriculum value of aligned Portfolios assessment.
  - Value of practice learning endorsed
  - Motivation for marking students final Portfolios
  - Apply patient/user involvement theories

Endorsing the benefits of the Kolb learning cycle for all stakeholders.

Establishing communities of practice (theories of social learning)

- Create communities of IPE practice-based learning linking HEIs to practitioner teams
- Greater awareness of value-base for social and health student curriculum

- Establishing communities of practice (theories of social learning)
  - Create communities of IPE practice-based learning linking HEIs to practitioner teams
  - Greater awareness of value-base for social and health student curriculum
